No entrance fee to those joining within 12 months of registration

An additional subscription will secure indemnity in respect of practice overseas

Full particulars and application form from—

Secretary, VICTORY HOUSE, LEICESTER SQUARE, W.C.2 GERrard 4553 & 4814

Marmite in Nutritional Retrobulbar Neuritis

For some years Marmite has been recognised as a preventive and curative agent in the nutritional retrobulbar neuritis found among certain native populations, and lately encountered among P.O.W.s and internees in the Far East during captivity and also since their release.

Experience has shown that early treatment with Marmite will usually restore visual acuity and make complete recovery possible in those cases where irreversible changes have not already taken place. The efficacy of Marmite in combating this condition is ascribed to its high content of vitamins of the B_2 group.

MARMITE

yeast extract

contains

Riboflavin (vitamin B_2) 1·5 mg. per oz.
Niacin (nicotinic acid) 16·5 mg. per oz.

Jars : 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9
Obtainable from Chemists and Grocers
Special terms for packs for hospitals, welfare centres and schools

Literature on application

THE MARMITE FOOD EXTRACT CO., LTD.

THE MINISTRY OF FOOD

Vitamin Supplements

The Welfare Foods Service operated by the Ministry of Food in consultation with the Ministry of Health provides the following supplements for expectant mothers and young children.

CONCENTRATED ORANGE JUICE (5d. per bottle or free).

Expectant mothers can get one bottle (6 fluid oz.) every 9 days. Infants under 6 months can get one bottle every 4 weeks. Children over 6 months and under school age can get one bottle every 2 weeks.

This provides the following average daily amounts of vitamin C.

Expectant mothers 40 mg.
Infants under 6 months 13 mg.
Children over 6 months and under school age 26 mg.

COD LIVER OIL COMPOUND (with added vitamin D). Free. All the above classes can get one bottle every 6 weeks, providing the following average daily amounts of vitamins A and D.

Vitamin A 4,000 i.u.
Vitamin D 700 i.u.

CHOCOLATE COATED vitamin A & D Tablets (with added calcium phosphate B.P. and potassium iodide). Free.

Available to expectant mothers as an alternative to the cod liver oil compound.

The dose is one tablet daily, containing—

Vitamin A 4,000 i.u.
Vitamin D 800 i.u.
Calcium phosphate B.P. 250 mg.
Potassium iodide 0.13 mg.

The local Food Office will be glad to give full information about this service. Doctors are asked to bring it to the attention of expectant mothers and mothers of children under school age.

Professional enquiries should be addressed to The Ministry of Food, Welfare Foods Division, Mount Royal, Colwyn Bay.

Issued by the Ministry of Food, London, S.W.1.

---

in sulphonamide therap

lower dosage

greater safety

. . . are provided by 'Sulfamerazine' which requires approximately one half the usual dosage of sulphadiazin sulphathiazole.

This reduces sulphonamide therapy to simpler and m economical terms.

In diseases in which four to six doses of sulphadiazine other sulphonamides are given daily, the same therape results may be obtained with a minimum of inconvenie and at proportionately lower cost, by only two to th doses of 'Sulfamerazine'.

> **(1) Relatively infrequent and smaller doses are requ to maintain any given plasma concentration.**
>
> **(2) The urine concentration at any given blood level less than that of other sulphonamides in current use.**
>
> **For these reasons the possibility of drug concretions in urinary tract should be less with 'Sulfamerazine' t when other sulphonamides are used.**

'Sulfamerazine' is no more toxic than sulphadiazine ar less toxic than sulphathiazole and sulphapyridine. It remarkably effective in the treatment of infections caused b pneumococci, haemolytic streptococci, meningococc an gonococci.

'Sulfamerazine' is supplied in 0.5 grm. tablets for oral administration, in bottles of 50, 100, 500 and 1000. Sodium 'Sulfamerazine' sterile powder for intravenous administration is supplied in 5 grm. vials and in 50 c.c. ampoules of a 6% solution.

Whom shall I ask to be my Executor or Trustee?

This is a question which comes to us all. We must find someone whom we can trust implicitly, someone whose ability to complete the task is beyond all doubt and whose sympathy will remove any anxiety which may be felt by those we leave behind. Barclays Bank fulfils all these requirements and has for many years provided a valuable service for its Customers by acting as Executor and Trustee, either alone or jointly with others.

Full information may be obtained from any Branch or from the Trustee Department:

ACID MILKS IN INFANT FEEDING

The wealth of buffer substances in milk results in the absorption of considerable quantities of acid in the digestive tract. In certain cases it is reasonable to give the infant the kind of nourishment which necessitates the least effort, and controlled acidification offers a means of reducing demands on the secretory functions. In view of the varied nutritional needs of infants requiring acid milk, the following range of products is available :—

BEURLAC
A buttermilk in powder form, useful for infants suffering from gastric disorders.

PROLAC
Of approximate half cream fat standard, but with increased protein, as required in gastro enteritis.

LACIDAC

SEPARATED
Almost fat free. Invaluable in cases of fat intolerance.

HALF CREAM
An intermediate grade for less severe cases and for graduation to normal feeding.

FULL CREAM
Suitable for long term use, or as a final stage of graduation to normal feeding.

★ *Particulars of these and other Cow & Gate preparations for specialised infant feeding, will be gladly forwarded on request.*

VITAMIN C B.D.H.

A generous intake of vitamin C is necessary to promote the efficient utilisation of proteins and to ensure adequate 'antibody' formation, thus preventing recurrent infection and maintaining maximum resistance to bacterial invasion.

KEEPING HIM ON THE JOB . . .

It is recognized that hæmorrhoids rank comparatively high among the causes of lost "man hours." Whenever non-surgical treatment is indicated, Anusol may be used with the knowledge that it will afford the kind of relief likely to keep the patient on his job. By their emollient properties Anusol Suppositories reduce inflammation, alleviate pain and check hæmorrhage. They contain no narcotic or anæsthetic to give the patient a false sense of security, but give relief and lessen discomfort during defæcation.

ANUSOL Haemorrhoidal Suppositories

The Anusol suppository base melts at normal rectal temperature.

WILLIAM R. WARNER & CO. LTD., POWER ROAD, LONDON, W.4.

Efficient Salicylate Medication

'ALASIL' is an analgesic, antipyretic and sedative of established value. It provides the physician with an efficient form of salicylate medication which combines the advantages of high tolerability and greater freedom from the possibility of unpleasant gastro-intestinal sequelæ.

This tolerability is due to the fact that 'Alasil' is a combination of acetylsalicylic acid and Dibasic Calcium Phosphate together with 'Alocol' (Colloidal Aluminium Hydroxide), an effective gastric sedative and antacid

For these reasons 'Alasil' can be administered with confidence—over prolonged periods if necessary—to children, adults, the aged, and patients with finely balanced digestive capacities.

Alasil

A PRACTICAL TEXTBOOK OF LEPROSY

By R. G. COCHRANE, M.D., F.R.C.P. (Lond.), D.T.M. & H. (Eng.)

With a Foreword by

Sir GEORGE McROBERT, C.I.E., M.D., F.R.C.P., D.T.M. & H., Lt.-Col., I.M.S.

Pp. 288 174 Illustrations 42s. net

OXFORD UNIVERSITY PRESS

Research on the value of certain food products in stimulating metabolism

STRIKING RESULTS OF CLINICAL TESTS

A famous clinical research institution agreed to conduct tests to find out the comparative value of various food products — broths, meat extracts etc. — commonly prescribed for stimulating metabolism.

Normal men and women were chosen as subjects and their basal metabolism established. Various well-known preparations for stimulating the metabolism were administered and the results assessed by a basal metabolism apparatus.

The results were striking, for they revealed that *one* meat preparation was outstandingly successful in raising the rate of metabolism. It was Brand's Essence.

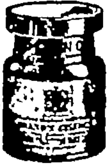
The apparatus showed that after ingestion of Brand's Essence there was a sharp increase in heat output, reaching a peak after half an hour, still appreciable six hours later.

Proof was thus established that Brand's Essence effectively stimulates metabolism — to an extent not shared by other accepted meat preparations.

For over 100 years Brand's Essence has been recommended by doctors. *You* can prescribe it with confidence when there is need for a natural metabolic stimulant that makes no demands on the digestion.

IMPORTANT TO DOCTORS

Brand's Essence is extracted from the finest lean meat. It contains 10% of easily assimilable protein, and is rich in extractives such as creatine, carnosine, etc. It is free from fat and carbohydrate and has a low salt content. Brand's Essence quickly absorbs the excess free acid of the gastric juices, and for this reason it can be prescribed even in cases of acute digestive disorder.



Brand's Essence

"OXOID"
Therapeutical Preparations

"OXOID" Brand
DIENOESTROL

Use *For the treatment of*

- *MENOPAUSE*
- *MENSTRUAL IRREGULARITIES*
- *UTERINE INERTIA*
- *SUPPRESSION OF LACTATION*
- *AMENORRHOEA*
- *PROSTATIC CANCER*

Supplied

Tablets — 0.1 mg., 0.3 mg. 1.0 mg., 5.0 mg.

Notes

As this preparation is highly active in small doses, the desired effects can be obtained without toxic reactions. "Oxoid" Stilboestrol and "Oxoid" Hexoestrol are also available.

OXO LIMITED (Medical Dept.),
Thames House, Queen St. Place, London, E.C.4

Warning

VEGANIN is a Registered Trade Mark (No. 469189), the property of William R. Warner & Co., Ltd., Power Road, London, W.4. The use of the name "Veganin", or of such terms as "Proveganin", to describe tablets not made by us, is an infringement of our legal rights and tends to deception of the public.

ANAHÆMIN B.D.H.

The treatment of pernicious anæmia with Anahæmin B.D.H. is characterised by—

1 the small volume of effective doses
2 the infrequency of maintenance doses
3 comparative freedom from reactions

Each batch of Anahæmin B.D.H. is clinically tested before issue

THE BRITISH DRUG HOUSES LTD. LONDON N.1

FOR THE BUSY PRACTITIONER

The convenience of tablet medication is undoubtedly of marked value in the treatment of many conditions presented daily to the physician.

This is particularly true of alkaline therapy, where 'Milk of Magnesia' Tablets are a frequent and everyday prescription. In the busy dispensary, or for providing immediate symptomatic relief while visiting the patient's home, they present advantages readily appreciated by the practitioner.

Quickly dispensed, accurate in dosage and convenient to take during working hours, 'Milk of Magnesia' Tablets offer a simple yet efficacious means of combating gastric upset due to hyperchlorhydria.

SPECIAL PROFESSIONAL PACKS

For personal, surgery or dispensing use, a professional pack of 'Milk of Magnesia' Tablets is available. This contains 500 Tablets and costs 8/9d. (including tax) post free. Orders should be sent direct.

'MILK OF MAGNESIA' TABLETS

THE CHAS. H. PHILLIPS CHEMICAL CO., LTD., 1, WARPLE WAY, LONDON, W.3

★ *'Milk of Magnesia' is the trade mark of Phillips' preparation of magnesia.*

"HEWLIX"

BRAND TRADE MARK

VITAMIN ELIXIR

A pleasant and palatable tonic readily taken by children and patients of all ages and especially valuable during convalescence

Made by a modern homogenising process, "HEWLIX contains vitamins A and D, Glycerophosphates, Organic Iro and Calcium, with traces of Copper and Manganese, in deliciously flavoured syrup containing glucose.

Indicated in debilitated conditions and in convalescence afte illness or operations. "HEWLIX" provides the vitamins an minerals necessary for a rapid recovery.

In amber bottles of 8, 20 and 90 fl. oz.

MANUFACTURED ONLY BY

C. J. HEWLETT & SON Ltd., 35-43 Charlotte Road, LONDON, E.C

Also at 48, CARSTAIRS STREET, GLASGOW, S.E.

The Control of Scabies

with

'TETMOSOL'

brand

Tetraethylthiuram Monosulphide

'Tetmosol' is a powerful sarcopticide, and in the forms of 'Tetmosol' Soap and 'Tetmosol' Solution has proved highly effective in both the prophylaxis and treatment of scabies

The Solution (25%), diluted with water before use, provides a most satisfactory and certain method of treatment. It produces a rapid cure of scabies and has the advantage that its application is painless and rarely gives rise to dermatitis

'Tetmosol' Soap—a pleasantly perfumed soap tablet containing 5% tetraethylthiuram monosulphide—is primarily intended for prophylactic use against scabies It has proved especially valuable for controlling outbreaks of the disease in families and in communities such as asylums, hospitals, schools, etc. The method of use is simple and convenient so that the co-operation of the scabies patient is readily secured

'Tetmosol' Solution (25%) Bottles of 100 c.c., 250 c.c. and 2 litres

'Tetmosol' Soap (5%) Single 3 oz. tablets and boxes of 36.

Literature supplied on request.

SevenSeaS is vitamins *plus*

Popular belief always credited Cod Liver Oil with nutritional values over and above those of the Vitamin A and D that it contains in abundance Recent scientific research has justified an ancient belief in yet another specific direction.

Unsaturated fats (and Cod Liver Oil is more unsaturated than any other edible oil or fat) are often deficient in normal diets. They have special values in promoting general health and particularly the proper nutrition and health of the skin.

The method of preparation of SevenSeaS at sea from sea-fresh livers ensures that the delicate unsaturated fatty acids of the oil are presented in an undamaged and readily digestible form. A daily teaspoonful of SevenSeaS provides unsaturated fatty acids at the recommended minimum level of approximately 1% of the calorie intake.

Current rationing difficulties make the prescription of SevenSeaS of still greater value.

STANDARD OIL:
Vitamin A 20,000 I.U.; Vitamin D 2,500 I U per oz.
CONCENTRATED:
Vitamin A 60,000 I U.; Vitamin D 6,000 I U per oz.

Have pleasure in announcing that they are undertaking the distribution of

EXCERPTA MEDICA

Fifteen Journals containing pertinent and reliable abstracts in English of every article in the fields of Clinical and Theoretical Medicine in every available medical journal in the world.

A detailed prospectus with full particulars of the various sections will be gladly forwarded on application.

A SELECTION OF INTERESTING MEDICAL BOOKS

MEDICINE
By A. E. CLARK-KENNEDY, M.D., F.R.C.P. Complete in Two Volumes. Sold separately. Volume I. Just Published (Volume II. Ready Spring 1948.) 20s.

ATLAS OF BACTERIOLOGY
By R. CRANSTON LOW, M.D., F.R.C.P.E., F.R.S.E., and T. C. DODDS, F.I.M.L.T., F.I.B.P., F.R.P.S. 168 Illustrations, 167 in full colour. 32s. 6d.

RETROPUBIC URINARY SURGERY
By TERENCE MILLIN, M.A., M.Ch. (Dublin), F.R.C.S., F.R.C.S.I. Royal Med. 8vo. 220 pages. 163 Illustrations. 25s.

PATHOLOGICAL HISTOLOGY
By ROBERTSON F. OGILVIE, M.D., F.R.C.P., F.R.S.E. Third Edition. 260 Photomicrographs in colour. 37s. 6d.

ILLUSTRATIONS OF REGIONAL ANATOMY
By E. B. JAMIESON, M.D. Seventh Edition, in seven separate sections or one bound volume. 320 coloured Plates. 75s.

CLINICAL PRACTICE IN INFECTIOUS DISEASES
By E. H. R. HARRIES, M.D., F.R.C.P., and M. MITMAN, M.D., F.R.C.P. Third Edition. Demy 8vo. 692 pages, fully illustrated. 22s. 6d.

WRIGHT'S PUBLICATIONS

Just Published 196 pp. 4¾ × 7¼ in.
10s. net; postage 4d.

HEALTH SERVICES IN ENGLAND

By R. C. WOFINDEN
M.D., B.S., D.P.H., D.P.A.

The basis of this book was an essay which was awarded the Joseph Rogers Prize in 1946. The addition of a chapter on the National Health Service Act of that year brings it thoroughly up to date.

Just Published Fourth Edition Fully Revised
8¾ × 5½ in. 464 pp. 346 Illustrations, 19 in Colour
30s. net; postage 8d.

SYMPTOMS AND SIGNS IN CLINICAL MEDICINE

An Introduction to Medical Diagnosis

By E. NOBLE CHAMBERLAIN
M.D., M.Sc., F.R.C.P.

"A copy of the new edition should find a place ... on the desk of all practitioners."—*Practitioner.*

Bristol: JOHN WRIGHT & SONS LTD.
London: SIMPKIN MARSHALL (1941) LTD.

NEW CASSELL BOOKS

THE REHABILITATION OF THE INJURED

Vol. 2. Remedial Gymnastics

By JOHN H. C. COLSON, M.C.S.P., M.A.O.T.

This volume, which follows *Occupational Therapy*, covers the use of specific remedial exercises in the after-treatment of fractures and other traumatic conditions.

"Colson's work represents an important part of a pioneer development in Great Britain—a development which is now being recognized and emulated throughout the world."—Sir R. Watson-Jones.

568 *pp.* 439 *text-figures* *Demy* 8*vo* 30*s. net*

THE DOCTOR AND THE DIFFICULT ADULT

By WILLIAM MOODIE, M.D., F.R.C.P., D.P.M.

With the increasing complications of modern life and the consequent inhibitions and repressions to which people are subject, the doctor is sometimes faced with difficulties of a complicated nature. Dr. Moodie deals with a number of the more common forms, and in a series of cases describes symptoms and suggests advice and treatment.

No entrance fee to those joining within 12 months of registration
An additional subscription will secure indemnity in respect of practice overseas

Full particulars and application form from—
The Secretary, VICTORY HOUSE, LEICESTER SQUARE, W.C.2. GERrard 4553 & 4814

for B_2 vitamins

MARMITE

yeast-extract

Among the nutrients known to be essential for the maintenance of health—mental as well as physical—are the vitamins of the B_2 group. Marmite contains riboflavin (1.5 mg. per oz.) and niacin (16.5 mg. per oz.) and also the less well-known B_2 factors such as pyridoxin, pantothenic acid, choline, biotin and folic acid, combined together in a palatable extract.

Present conditions are causing the medical profession to pay considerable attention to food in preventive and curative medicine. Marmite is therefore being prescribed increasingly for private and hospital patients and, as vitamin supplements are specially indicated for mothers and children, it is ordered widely in welfare centres, schools and nurseries.

Jars · 1-oz 8d., 2-oz. 1/1, 4-oz. 2/, 8-oz. 3/3, 16-oz. 5/9 Obtainable from Chemists and Grocers
Special terms for packs for hospitals, welfare centres and schools

Trufood Products of Repute

For premature and delicate babies

SECWAY

(DRIED SWEET WHEY)

For all conditions and diets where fresh whey would normally be used.

Secway presents the solids of fresh whey in the form of a readily soluble powder. It has the advantage that when reconstituted with water the percentage of total solids may be varied as required. Secway used in combination with Humanised Trufood provides a milk of any desired fat content.

ANALYSIS:

Whey Proteins	13%
Milk Sugar	76%
Milk Salts	9%
Fat	1%
Moisture	1%

1 oz. of powder contains:

Calcium	175 mg.
Phosphorus	175 mg.
Calories per oz.	106

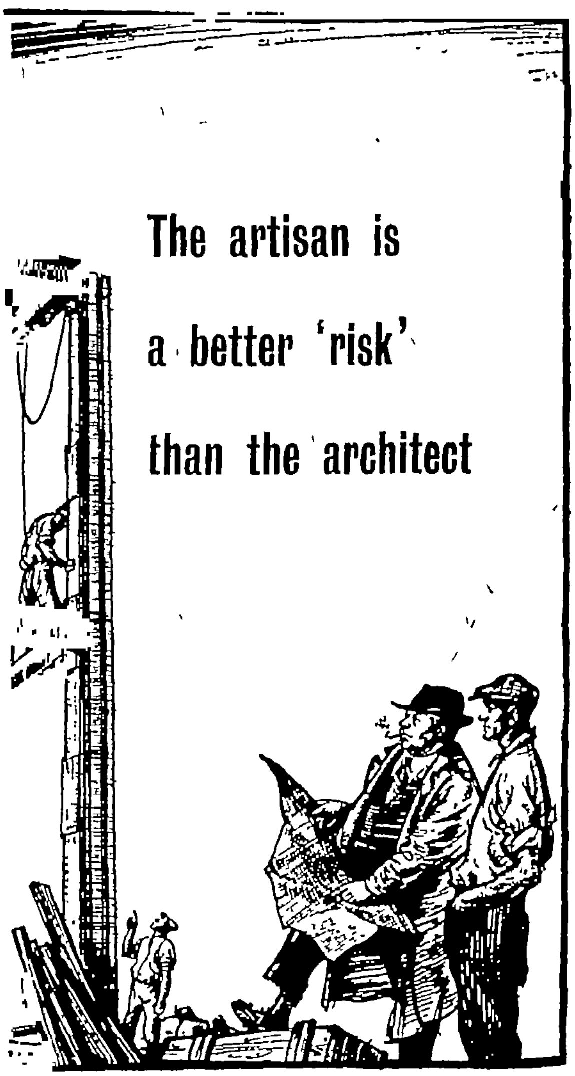
TRUFOOD LIMITED (Dept. SL 30)
BEBINGTON, WIRRAL, CHESHIRE

TFS 303/7



In comparison with the population as a whole, the professional classes seem especially prone to Diabetes Mellitus.

In the treatment of Diabetes Mellitus, the use of Insulin is now universal. Insulin-Boots is prepared from pure crystalline Insulin and tested in accordance with the regulations made under the Therapeutic Substances Act, 1925.

Supplied in rubber-capped vials as below:

20 *units per c.c.*	Vials of 5, 10 and 25 c.c.
40 *units per c.c.*	Vials of 5 and 10 c.c.
80 *units per c.c.*	Vials of 5 and 10 c.c.

Boots **INSULIN-BOOTS**

Further information concerning Insulin-Boots gladly sent on request to Medical Department, BOOTS PURE DRUG COMPANY LIMITED, NOTTINGHAM

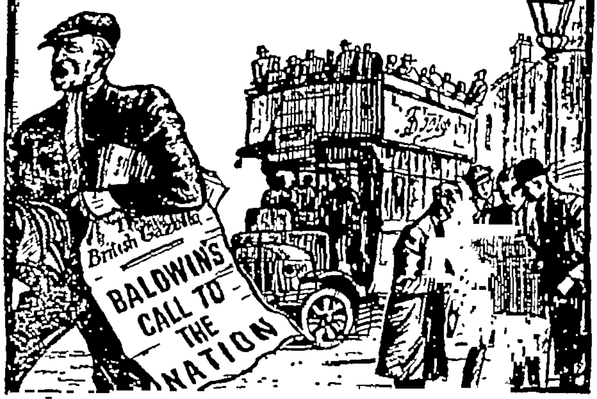
The news that DIDN'T get into the papers . . .



The British Gazette
BALDWIN'S CALL TO THE NATION

To the general public, the outstanding topic of 1926 was the General Strike. To the medical profession, however, the year was also memorable for another event of far-reaching importance.

Until Minot and Murphy discovered the curative value of liver in 1926, little was known regarding the treatment of macrocytic anæmias, and prognosis was very grave. Since then the curative effects of liver have been fully proved.

Hepastab Forte is a concentrated extract of liver which has been produced in Boots' laboratories after extensive experimental work. Its high purity excludes risk of undesirable reactions *following administration, and it is painless on injection.*

Hepastab Forte is indicated in cases of pernicious anæmia and other megalocytic anæmias. One cubic centimetre is therapeutically equivalent to 4,000 to 5,000 gm. of fresh liver by the mouth.

HEPASTAB FORTE Brand
CONCENTRATED LIVER EXTRACT

Further information from the Medical Department,
BOOTS PURE DRUG COMPANY LIMITED, NOTTINGHAM.
D-10

Indifference to food . . .

is an indication for

ELIXIR 'VIRVINA'

a palatable elixir of the vitamin B complex with glycerophosphates.

Each fluid ounce of Elixir 'Virvina' contains:

Thiamine hydrochloride (Vitamin B_1)	4.0 mg. (1332 I.U.)
Riboflavin (Vitamin B_2 or G)	2.0 mg.
Pyridoxine hydrochloride (Vitamin B_6)	0.1 mg.
Nicotinic Acid Amide	30.0 mg.
Calcium, Sodium, Potassium and Manganese glycerophosphates (total)	6.625 grains

Elixir 'Virvina' stimulates the appetite, improves digestive functions and corrects deficiencies of the vitamin B complex. It is unusually palatable and may be administered regularly as a dietary supplement especially during childhood, pregnancy, convalescence and old age, when the body's requirements for minerals and for the factors of the vitamin B complex are above normal.

Elixir 'Virvina' is supplied in 4 oz., 16 oz. and 80 oz. bottles. Informative literature will be supplied on request.

QUARANTINE, INCUBATION, AND ISOLATION AT SCHOOL

R. E. SMITH
M.B. Camb., F.R.C.P.
MEDICAL OFFICER, RUGBY SCHOOL; PRESIDENT, MEDICAL OFFICERS OF SCHOOLS ASSOCIATION

HISTORY is full of references to isolation and quarantine. The earliest is in the 13th, 14th, and 15th chapters of Leviticus, recording how Moses and Aaron with divine inspiration gave the children of Israel most precise instructions for isolation, quarantine, and observation of him who "shall have in the skin of his flesh a rising, a scab, or bright spot," "like the plague of leprosy," and for "any man who hath a running issue of his flesh." Other public-health measures described are the disposal of fomites and the disinfection of the patient and of the house. We can only speculate what these diseases were; but when we remember it was not until the end of the seventeenth century that Sydenham separated measles from scarlet fever, we can better understand Moses's failure to be more clinically accurate.

War has always presented epidemiological problems. The returning Crusaders spread leprosy far and wide, and history records fewer more pathetic stories than the perpetual isolation of lepers. In the sixth and seventh centuries France and Lombardy had established leper houses, where the miserable victims of this dire disease were condemned to exile. Richard the First's glorious failure was followed by an increase of leprosy, and cruelly applied, if well-meant, measures of isolation added horror to those who already felt themselves branded by a curse from heaven. Inhuman laws invariably provoke reaction, and in 1346 the proclamation that "all lepers must within fifteen days betake themselves to places in the country, solitary and notably distant from the said city and suburbs, and take up their dwelling there" shows the law was being circumvented.

Soon a greater menace, plague, relegated leprosy to a minor rôle. Ragusa, on the Adriatic, first enforced quarantine for plague in 1377. Ships arriving from the Levant and from Egypt were isolated at special ports, and passengers were detained at the port for thirty (later forty) days. Inland cities also imposed quarantine, and Milan attributed its freedom from the Black Death until 1350 to the extreme strictness of her communications. England did not impose quarantine until 1663, when it was decreed that vessels "coming from infected ports should not be permitted to come nearer than Gravesend." Pepys recorded in his diary (Nov. 26, 1663) that the Admiralty instituted quarantine for the first time—"All ships arriving from Amsterdam or other infected places being made to perform their quarantine of thirty days," as Sir Richard Browne expressed it in the Order in Council. Pepys recognised that this was "contrary to the import of the word, though in the general acceptation it signifies now the thing, not the time spent in doing it." Within two years of the enforcing of these laws the Great Plague showed how vain were the efforts to exclude infection. In the next two hundred years several attempts were made to abolish quarantine. The agitations had important repercussions, the chief of which were general health measures to relieve "the epidemic atmosphere."

The first scientific paper read to the Medical Officers of Schools Association was by J. Andrew in 1884 on "Infectious Diseases in School," and in the subsequent discussion many members expressed the view that certificates stating that a child had not been exposed to infection were useless. Nevertheless, that generation revered isolation and quarantine, as may be instanced by their requiring fourteen days' quarantine for scarlet fever, while some thought three months necessary for its isolation. The next year the first edition of our code of rules was published, and comparison between it and the tenth edition shows that, though scientific knowledge alters our views, bacteriological researches are second in importance to a study of the biological aspect of disease.

EFFECT OF ABOLISHING QUARANTINE

The lessons of the past are surely that we have neglected the natural history of the common infectious diseases and have been guided far too much by prejudice and safety-first measures. My predecessor at Rugby School, Dr. A. I. Simey, felt that there was no justice in schools sending boys home after they had been exposed to infectious diseases at school if the school did not take them back in similar circumstances, and therefore before I came to Rugby quarantine had been abolished. It was an act of faith based on impressions, but statistics later vindicated the policy. Table I shows our experience. From 1933 to 1947, of 203 boys exposed to infection, about half had had no previous attack. If quarantine had been strictly observed, 4224 days would have been lost, not all at school, but the child in quarantine in the holidays is often treated as an unwanted playmate. Those school authorities which still impose quarantine make little allowance for a previous attack. If only those not considered immune were excluded, 2123 days would have been lost. Only 3 boys developed the disease, 2 at the end of the holiday and 1 at school got mumps, but this last boy was isolated on the first day and no secondary cases appeared. In sixteen years we had 75 outbreaks of infectious diseases, and not one of the originators had the slightest idea he had been exposed to infection.

The figures show that quarantine is extremely wasteful, and that epidemics come like thieves in the night. Even supposing, for the sake of argument, that we had three epidemics of measles, whooping-cough, mumps, rubella, and chickenpox attributable to abolishing quarantine, the question still arises whether our policy has failed.

Table II shows the expectation of infectious disease among 513 boys leaving the school. It demonstrates that measles and whooping-cough are what one may call inevitable diseases. The 20 who did not get measles were probably immune, for nearly all of them had been through several epidemics. The way this immunity is gained in the majority is still doubtful. It is probable that many of those who escaped chickenpox were similarly immune. We know the whoop is not a necessary part of pertussis, so much so that Gardner (1936) would like to abolish the term "whooping-cough" altogether. Besides the 382 who were known to have had pertussis, many were said by their parents to have had doubtful attacks. These doubtful attacks appear to give immunity and must therefore be considered as attacks.

These 513 boys, except a few who were superannuated, spent five years at Rugby, where quarantine was not enforced, provided those exposed to infection were kept away from the source as soon as it was recognised. My submission is that, if by mischance we had been unfortunate enough to introduce infection into the school, the figures would not have been radically altered.

A study of disease by age-groups reveals additional reasons for modifying quarantine. The case-mortality from measles is 8% in the first two years of life, falling to 2% in the third, and thereafter to only a fraction of 1%. Whooping-cough has the same high case-mortality in the early years, and children are specially liable to be attacked by whooping-cough as distinct from measles in the first two years of life. Among the 513 boys investigated none had had measles in the first year and 15 in the second, whereas 14 had had whooping-cough in the first year and 15 in the second. It is our duty to postpone measles and whooping-cough until after the age of three years, which includes the first year of nursery

The Chas. H. Phillips Chemical Co. Ltd

For many years the Chas. H. Phillips Chemical Company has devoted its special resources to perfecting a range of antacid products for the alleviation of hyperacid conditions in patients of all ages.

These preparations by their consistently high quality have earned the confidence of the Medical Profession, and by their proved efficacy have gained wide acceptance from men and women in all walks of life.

An antacid dentifrice, the development of which has provided a parallel activity of the company, has gained similar support, and is recommended to young and old alike by the majority of the Dental Profession.

The Chas. H. Phillips Chemical Company is resolved rigidly to maintain those high standards which have built up through the years a reputation of which they are justly proud.

'MILK OF MAGNESIA' *(Regd.)*
The ideal antacid sedative for acute and chronic dyspepsia.
'Milk of Magnesia' is invaluable for securing rapid control of nausea and biliousness. It possesses mild laxative properties which ensure elimination of toxic degradation products.

'MILK OF MAGNESIA' TABLETS
A highly convenient and readily accepted method of securing effective alkalization in those instances where treatment must be maintained at frequent intervals throughout the day.

'PHILLIPS' DENTAL MAGNESIA' *(Regd.)*
Used daily as a mouthwash, 'Milk of Magnesia' affords invaluable protection against caries and erosion by combating the destructive influence of the acid-producing bacilli.
Phillips' Dental Magnesia is the only tooth paste containing 'Milk of Magnesia.'

'MIL-PAR' *(Regd.)*
This antacid lubricant—a skilfully prepared combination of liquid paraffin and 'Milk of Magnesia'—is indicated in chronic constipation and acid indigestion due to disorder of the alimentary tract.

r example, unmerited attention was given to the case ported at the Clinical Society of London in 1893, when boy spent an evening at a friend's house, leaving at ast four days before he developed mumps, but his friend t mumps 23 days after the visit. This is the only record here infectivity appeared more than 24 hours before e appearance of the swelling. Our chief concern is e duration of infectivity after the parotitis has appeared.

umps

Table IV gives details of 14 boys who went home between e tenth and fifteenth day after the appearance of mumps, d shows that, though most of them went home on the ird or fourth day after the swelling had subsided, none the 25 relations with whom they came in intimate ntact developed mumps. Mumps appears to be not fectious after the swelling subsides, and I submit that is the enforced isolation of the extra three or four days sually recommended which is so tedious for a healthy oy. These figures mean no more than that mumps is ot infectious three days after the swelling subsides. t may well be shorter, and a well-planned experiment ased on cultivation of the virus in the chick embryo hould decide the length of time the virus is present in he mouth.

Measles

We are equally ignorant about the length of infectivity f measles. In reviewing school measles in 1944 I nade a special point that catarrh in healthy schooloys was conspicuous by its absence, and this may ffect the length of infectivity of a disease which ssentially attacks the respiratory mucosa. Similarly, ttenuated measles, or the mild attacks so common at resent, may be infectious for a shorter time than are nore virulent attacks. The accompanying four charts how how mild measles may be, and indeed, if the emperature had not risen for a very short time to 103°F, ne could dismiss these infections as trivial.

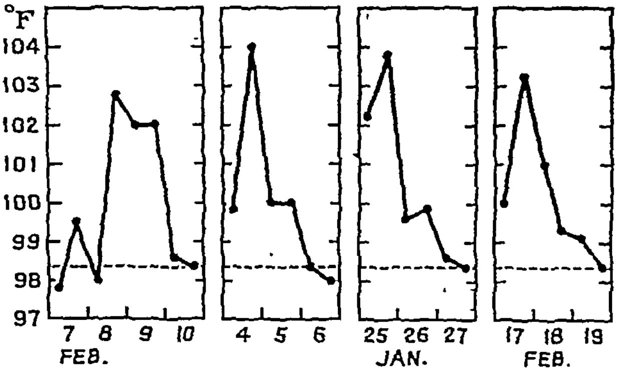
* 21, 22, 23 weakly positive

I have recently discharged boys with uncomplicated measles when I have considered them clinically free from infection, provided they have had four or five days' convalescence after their temperature has become normal. This may be from the tenth to the twelfth day. In the past boys have been discharged on the fourteenth day after the appearance of the rash, and many of these have gone home into households with non-immunes and not given rise to infection. A well-planned experiment, *once again using the chick embryo* as the cultivating medium, should determine the length of infectivity of measles. If this shows that measles is only infectious for a short time it will assist convalescence. Many parents are anxious that their children after measles should go to the seaside or other health resort for a change of air, &c., but their efforts are usually of no avail because the child is still considered infectious. Many schools, though they have accommodation for the sick, have no adequate accommodation for convalescents; but, if the patients recovering from measles could mix freely with those with accidents, &c., much time, labour, and fuel would be saved. I have never seen any harm come of sending boys back into school in the times I have specified.



Temperature charts in four cases of measles, showing transitory fever.

Rubella

Biological studies of viruses suggest that they change, probably by mutations, at a far greater speed than would be expected from the study of evolution on Darwinian lines, and the congenital deformities in the children of women with rubella, and the recent descriptions of the disease causing a somewhat more severe illness than in the past, may be new phenomena and not something which the older clinicians missed. Therefore we must be constantly prepared for change. What one says about rubella today may have to be modified later. In 1932 we isolated german-measles patients for the minimal time instead of the usual ten days. I was fortified by the knowledge that my predecessor had pursued the same policy in 1916 when he estimated the saving at 900 days. A comparison between long and short isolation shows it has little effect on the spread of the disease. Out of 340 in 1932 who had not had the disease, 84 (*24·7%*) were attacked despite a full isolation period of ten days, whereas in 1931, when boys were allowed to return to school after four or five days only, out of 442 who had not had the disease 116 (*26·2%*) were affected. This supports the belief that infectivity is short and raises the question of the site of incubation.

Chickenpox

Chickenpox is undoubtedly an airborne infection, but the virus may be present in the skin eruptions, and the clinical practice of allowing boys to return to school as soon as the scabs have healed is fully justified. This is common practice, and positive steps should be taken to make the skin healthy, capable of throwing off the infection as quickly as possible. Usually boys who have

nursed by the bed isolation method in multiple-bed wards. By setting aside small wards it might be possible to keep together patients who are all infected by the same serological type of streptococcus. The number of such wards would tally with the number (usually three or four) of epidemic types current at the time." This was written ten years ago and still generally remains a pious hope, but schools could adopt the principle of this recommendation by nursing their own patients, so preventing cross-infection, with the sequelæ of relapsing and return cases. If it is reasonably certain that the original infection has not been superimposed by a second or third serologically different type, a month seems ample time for isolation. In the only epidemic I have had of a streptococcal sore throat isolation for three weeks was enforced, with beneficial results.

For bacterial infection the length of isolation varies with many factors, all of which must be taken into account, but the two most important factors appear to be the health of the patient and the site of the lesion.

CONCLUSIONS

We must be realists over quarantine and base our policy on present knowledge and biological evidence.

It is our duty to persuade lay authorities that quarantine of exposed persons is wasteful, and that observation should succeed it.

Boys should be healthy, so that they resist disease with maximal efficiency.

When they fall ill with infection, it is our duty to isolate them for as short a time as possible but to provide ideal convalescence.

Our experiments in the first instance will be based on impressions and are justified only if we make observations to prove or disprove our theories. We will have to face occasional failures.

As I reread the writings of Dukes and Simey I realise my debt to them, especially to their having created an atmosphere with successive headmasters so that they, and the governing body, turn to their medical officers for guidance.

FURTHER OBSERVATIONS ON AN INHIBITORY SUBSTANCE (NISIN) FROM LACTIC STREPTOCOCCI

A. T. R. MATTICK
B.Sc., Ph.D. Lond.

A. HIRSCH
B.Sc. Reading

With a note by N. J. BERRIDGE, B.Sc., Ph.D. Birm.

From the National Institute for Research in Dairying, University of Reading

WE have already given some account (Mattick and Hirsch 1944, 1946) of the action *in vivo* of an inhibitory substance,* isolated from lactic streptococci, against streptococcal infections of the mouse. Later it was found that the substance was active in vitro against tubercle bacilli (Mattick 1946). We now describe the results of in-vivo trials with this and other pathogenic organisms, the method of large-scale preparation, and the toxicity of the inhibitory substance.

The earlier literature contains scattered references—some vague, some well supported—to the inhibitory action of lactic streptococci on other similar organisms, and Whitehead (1933) noted the inhibitory action of some milk streptococci on the "starters" used in cheese-making. He isolated and described the responsible substance as protein or polypeptide; but, though he noted that coliform organisms and spore-formers were unaffected, he did not determine its action against pathogenic organisms.

While our first note recording the action in vivo of the impure substance against pathogenic streptococci was in the press, Oxford (1944) published a paper describing some of the properties of a substance which he called diplococcin, isolated as a protein picrate from cultures of *Strep. cremoris*. This work was simultaneous with, but independent of, ours, and on conferring with Dr. Oxford we at first thought that the substances might be identical; but it now seems that they are different, inasmuch as our substance is prepared from the cell-free medium in which *Strep. lactis* has grown. It is stable towards ethyl alcohol and active against a wide range of micro-organisms. In contrast, diplococcin is prepared from *Strep. cremoris* and is partially inactivated by ethyl alcohol. In our experience more organisms are inhibited in vitro by the substances prepared from *Strep. lactis* strains than by those from *Strep. cremoris* strains.

It is clear that the lactic streptococci of group N (Shattock and Mattick 1943) and apparently those of other groups may produce several inhibitory substances (Thompson and Shibuya 1946). In this work we have observed that some organisms may inhibit others which are so closely related biochemically as to be virtually indistinguishable. For example, strains of *Strep. lactis*, *Strep. cremoris*, and organisms intermediate between these species may inhibit each other (table I).

STRAIN SELECTION

Several strains of inhibitory streptococci were investigated and found to give various yields. A strain was eventually found which gave good yields in broth and which has retained this property for two years at least. As adaptation to broth proceeds, yields of the inhibitory substances from growth in milk decline.

The strains used for large-scale production are kept in bullock's heart medium and usually need 3–5 transfers before the yield of antibiotic substance reaches its maximum. Strain to strain variation is well marked. Vacuum drying appears to be unsatisfactory, since the property of producing the inhibitory substance is lost. Freeze-drying has not yet been tried.

METHOD OF ASSAY

The Oxford cup method of Heatley (1944) could not be used for assay, because nisin does not diffuse through agar at about pH 7. A method of titration has therefore been devised. The test organism is a hæmolytic strain of *Strep. agalactiæ* grown in dextrose (1%)-'Lemco' (0·3%)-peptone (Evans 0·5%) broth, containing 0·5% NaCl.

Sterile portions of this broth are inoculated with 0·001% of a 24-hour culture of the test organism, giving 2000–10,000 viable organisms per ml. This bulk-inoculated broth is used to prepare serial dilutions of the substance under test, the dilutions usually being in powers of 2. Growth controls containing no inhibitory substance, and sterility controls containing inhibitory substance but no test organism, are incubated together with the test dilutions.

When the growth control shows visible growth at 37°C (usually 16–20 hours) the results are read, and the titre of the substance is taken as the dilution of the last tube in which growth is not visible.

UNITS

The results are now expressed as units, based on a standard partially purified preparation. One unit is taken as that amount of the preparation under test dissolved in N/20 HCl which gives the same inhibition as the standard preparation, also dissolved in N/20 HCl.

---

* Group N Inhibitory Substance: (G) Nisin.

chickenpox in the holidays are sent back three or four weeks after the rash has appeared, instead of about half the time in properly nursed boys. On one occasion I have had a boy (a doctor's son) sent back to school with some spots not healed. As it was over a fortnight since the rash had appeared, he was allowed to stop; but cases of chickenpox appeared in his house after the usual incubation period.

Poliomyelitis

The length of infectivity of poliomyelitis must be short, as cases admitted to general hospitals almost never give rise to other cases. This has little effect on policy, because the length of treatment far outstretches the length of infectivity.

LENGTH OF INFECTIVITY OF SOME BACTERIAL DISEASES

Scarlet fever, whooping-cough, and Sonne dysentery are three examples of bacterial infections which are common in schools. In estimating the length of infectivity bacteriology can guide, but our conclusions must rest on a study of the natural history. Climatic conditions and the health of the tissue attacked will influence the length of infectivity. Healthy respiratory mucosa and intestines will recover more quickly than those which have been abused by constant irritation either from dust or from purgatives.

Sonne Dysentery

Sonne dysentery usually follows the ingestion of infected food and was comparatively poorly recognised until 1930, though Sonne first described his organism in 1915 and Paterson and Nabarro (1922) recognised that some of the infectious diarrhœa in very young children was due to an organism closely resembling Sonne's bacillus which they called *B. coli anaerogenes*.

In an epidemic in 1931, 21 boys were attacked. Stool culture proved positive only in those who had subsequent diarrhœa, and not in those who only vomited. One boy, who could not accurately date the onset of his symptoms but certainly had nausea on July 15 and diarrhœa on July 16, had on an average two diarrhœic motions a day until July 23, when he first reported sick. Sonne organisms were cultivated from a stool passed on the 23rd, but as soon as he was put to bed he recovered uneventfully. There were no subsequent cases from these boys who went home at the end of term—i.e., fourteen days after the start of the epidemic, but in some instances only ten days from the onset of diarrhœa.

In February, 1936, 7 boys were attacked with typical Sonne dysentery from whom the organisms were cultivated in 6 cases. Specimens obtained after a saline purge were examined a fortnight later and all were negative, except in the case of one boy who became a temporary carrier, whose stools were negative a fortnight later, as they were again three months later when he had an unexplained attack of diarrhœa.

Since then I have had other epidemics and taken similar precautions to find out bacteriologically if the stools are still infectious; but I always send boys back to school when they are clinically free from symptoms, making them realise that they have had an intestinal infection, and that it is necessary for them to give their hands a thorough scrub after having been to stool. They have never given rise to return cases.

It is possible that people may become true Sonne carriers, but the only suspicious person who would fall into this class was a boy of 15½ who, on Feb. 18, 1934, was admitted with diarrhœa four times and a temperature of 102°F. Next evening he passed a stool containing blood and mucus from which *B. dysenteriæ* was obtained. He had had three similar previous attacks but has had none since. There have never been any other cases of Sonne dysentery in this boy's house. Purgatives or even regular aperients are never taken at Rugby and it may be because these boys have healthy intestines that they throw off the infection very quickly.

The management of Sonne dysentery in England can be summed up thus: early diagnosis, rest and warmth in bed on a generous diet, early discharge after the cessation of symptoms, and hygienic disinfection of hands after possible contamination.

Whooping-cough

In our only large epidemic of whooping-cough, in July, 1935, catarrhal symptoms were absent, and vomiting and whooping were infrequent. Table v indicates the length of infectivity of whooping-cough. The days are counted from the very earliest cough, before it would give rise to the suspicion of whooping-cough except in an epidemic.

Whooping-cough is infectious from an early stage but quickly loses its infectivity, and by the time the whoop arrives the child is probably free from infection though he may still be ill. Convalescence is often sorely needed, but usually nobody will have the child because of the symptoms.

Scarlet Fever

A streptococcus has now been proved to be the cause of scarlet fever. Streptococcal sore throat without rash demands the same management as scarlet fever. In schools the problem is different from that in fever hospitals, but all of us must have read the article by Allison and Brown (1937) with real interest. They showed as clearly as possible that relapses in scarlet fever during stay in hospital was due to a reinfection by a streptococcus of a serologically different type from that producing the primary infection. The diminution of the number of return cases by early discharge was due to the fact that the longer children stayed in a fever hospital the more liable they were to be reinfected by a streptococcus of a different serological type.

My experience of scarlet fever includes 13 outbreaks. Two of these were single cases of surgical scarlet fever isolated for seven and fifteen days. In the remaining eleven outbreaks, 35 boys were attacked. The shortest isolation was twenty-one days (2 cases); 14 other patients were isolated for less than four weeks, 8 others for less than five weeks, and 11 others for less than six weeks. The types of streptococcus differed on only one occasion, when two boys affected shared a four-bed ward and were both advised for their own sakes not to cough at one another. They were discharged on the twenty-sixth and twenty-seventh days without any untoward results. There were no relapses.

Bacteriological examination of the nasopharynx of children with scarlet fever must be correlated with clinical findings. The diagnosis should, if possible, be confirmed by finding a streptococcus and by determining its type. If the types are different, patients should be separated; but how long should one continue swabbing the throats? On one occasion, at the request of anxious parents, I did this at weekly intervals, but on the thirty-fifth day the swab was still positive. Nevertheless, the parents decided to take the boy home, and on the thirty-seventh day his mother fell sick with scarlet fever. Apart from this I have had no return cases, though the isolation has been shorter.

The lessons to be learnt are two: (1) to remember that the throat is a habitat of the streptococcus, and that the child should be trained not to cough over people, and fond parents should equally realise that they are liable to contract infection from their children; and (2) to realise that scarlet fever in *schools* is usually caused by the same type of streptococcus, and that the patients should therefore be segregated in the school sanatorium and not sent to fever hospitals. Allison and Brown (1937) suggested that scarlet-fever patients should be cubicle-nursed if possible: "failing this they should be

The impure preparations used in the in-vivo experiments with streptococci and tubercle bacilli reported here caused, on repeated subcutaneous injection, local œdema and necrosis. The much purer preparations (10^7 units per g.) used recently caused no visible lesions at the site of inoculation. No systemic effects were apparent.

IN-VIVO EFFECT AGAINST BACTERIAL INFECTIONS

Streptococci

It has been found that antibiotic substances from natural sources may be active in vitro but not in vivo. We considered it wise, therefore, to attempt to assess the probable value of nisin by using impure preparations for in-vivo experiments before embarking on fairly large-scale purification.

A very impure preparation was therefore used in a small experiment against a mouse-pathogenic streptococcus in vivo. A single dose of 2 mg. had well-marked curative effects.

A larger experiment with 20 control and 20 treated mice (each received 10,000 lethal doses) was then carried out. A total weight of 10 mg. given in doses three-hourly over 45 hours protected all the treated mice (all controls died within 24 hours), of which 40% survived after seven days, when the experiment was discontinued. In a further experiment, still using an impure preparation, the interval between doses was extended from 3 to 12 hours. It was found that similar protection was conferred.

When these experiments had been completed, it was found that cultures of streptococci in broth appeared to be sterilised within a few minutes of adding the substance.

Another experiment with mice was therefore carried out. The mice received 1000 lethal doses of a mouse-pathogenic streptococcus. After an interval of 12 hours the animals were moribund. They were then given a single dose of 50 mg. (100,000 units) of the impure substance.

TABLE II—CONCENTRATIONS OF NISIN REQUIRED TO INHIBIT IN VITRO SOME OF THE MORE IMPORTANT SUSCEPTIBLE ORGANISMS

Organisms susceptible	No. of strains or species	Units required to inhibit
Streptococci groups A–M except C, D, L	17	0·25–4
Pneumococcus, type I	2	0·25
" type II	2	100
Staph. pyogenes	6	100
Neisseria	3	2–50
Bacillus	6	2–4
Clostridium	8	0·25–80
Corynebacterium	12	4–120
Actinomyces	6	1–10
Mycobact. tuberculosis	6	100–500
Erysipelothrix monocytogenes	3	2

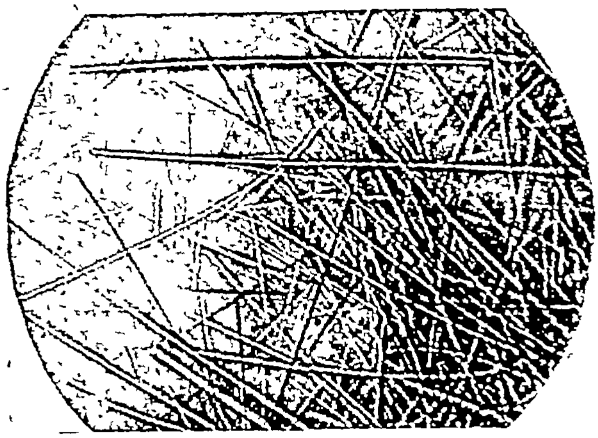
All the treated animals were alive after ten days, when observations ceased. Some of the control animals died within 16 hours, and all were dead within 30 hours.

Clostridium septicum

In a similar experiment with single doses of the substance against *Cl. septicum* there was also well-marked protection, and 40% of the animals which were moribund survived for at least ten days.

Strep. pneumoniæ

Encouraging results were also obtained in the same way with *Strep. pneumoniæ* (type II).



Photomicrograph of nisin crystals. (× 500.)

Mycobact. tuberculosis (human)

From the results of experiments in vitro it appears that the acid-fast organisms are considerably less susceptible than, for example, the streptococci. This, coupled with the nature of the lesions and the general chronicity of experimental tuberculosis, makes it difficult to decide, in the first instance, how doses should be administered and spaced. Conclusions can at present be only tentative.

In a four-a-side experiment with guineapigs using a virulent strain of the tubercle bacillus (C Weybridge) it was found that there was significant limitation, but not prevention, of infection by the impure material. The spleens of animals treated with six-hourly injections of 100 mg. for four weeks were found at necropsy, six weeks after infection, to be completely free from macroscopic lesions, whereas all the controls were obviously severely infected.

SUMMARY

An antibiotic substance, nisin, isolated from liquid cultures of *Strep. lactis*, is active in vitro against many types of pathogenic and other organisms.

A method of semi-large-scale preparation of the substance is described.

Even in the impure state, nisin is effective in vivo against infections with *Strep. pyogenes*, *Cl. septicum*, and type II pneumococcus.

Limitation of spread in experimental tuberculosis in the guineapig has also been observed.

We wish to acknowledge our debt to Miss E. M. Barnes, of Messrs. Benger's, for some of the data in table II, to Dr. H. C. Collumbine, of Messrs. Benger's, for observations on toxicity, and to Mr. L. J. Meanwell, of United Dairies, for strains of inhibitory streptococci.

Further Purification of Nisin

N. J. BERRIDGE

Experiments with active material prepared by a method similar to that described above showed that it could be further purified by precipitation at pH 6·1 from molar phosphate buffer. The requisite amount of potassium dihydrogen phosphate was added to a 5% solution of nisin in dilute hydrochloric acid at pH 1·8, and the pH was then raised to 6·1 with concentrated potassium hydroxide. The resulting precipitate had an activity of about 8,000,000 units per g. of organic dry weight. This precipitate, dissolved in dilute hydrochloric acid at pH 1·9, was fractionated by partial precipitation with sodium chloride, the portion of intermediate solubility having an activity of about 20,000,000 units per g. of organic dry weight. By repeated fractionation this figure was increased to 30,000,000.

Many attempts at crystallisation by the slow addition of sodium chloride to a solution of this material gave

(A 0·1% solution of the present standard preparation contains 10,000 units per ml. and has a titre of 1/10,000 by the *dilution method.*)

ORGANISMS SUSCEPTIBLE

The more important of these are shown in table II. The following pathogenic organisms have been found to be susceptible in vitro: streptococci of groups A, B, E, F, G, H, K, M, and N, staphylococci, *Micrococcus lysodeikticus*, pneumococcus, neisseria, some types of bacillus, clostridium, corynebacterium, mycobacterium, lactobacillus, actinomyces, and erysipelothrix. The activity of nisin against these organisms is fully maintained in media containing serum, blood, or milk. None of the gram-negative organisms so far tested is susceptible.

The relative sensitivities in vitro vary; as shown in table II, the mycobacteria are about 25–100 times less sensitive than the streptococci. It should be stated specifically, however, that, for example, cultures of tubercle bacilli in Long's medium are killed or rendered incapable of growth.

Similarly a growing culture of the streptococcus producing the antibiotic has been shown to kill or render avirulent the tubercle bacilli in milk (Mattick and Hirsch 1946). (The concentration of inhibitory substance reached in the milk was about 80 units per ml.)

MEDIUM FOR GROWTH

For semi-large-scale preparation of the substance the following medium is used:

Glucose	15 g.	KH_2PO_4	10 g.
'Yeastrel' ..	7 g.	$MgSO_4$	0·2 g.
Na citrate ..	6 g.	NaCl	3 g.
K_2HPO_4	10 g.	Tap water to	1000 ml.

pH 7·2

Before use the yeastrel is freed from an acid-soluble component by adjusting its solution to pH 8. This avoids an unnecessary contaminant in the later stages of preparation. No improvement in growth or yield of inhibitory substance is obtained by increases in yeastrel content beyond 0·7%.

This medium is inoculated (in large bulk) with about 1% by volume of a 24-hour growth of *Strep. lactis 354* in broth of the same composition and incubated at the optimal temperature of 30°C. The most favourable pH and the most favourable proportion of salts and of the nutrient components of the medium were determined by experiment. This medium was found to be unsuitable for the preparation of the substance associated with *Strep. cremoris*. Niven's (1944) synthetic medium was also tried and found to be satisfactory for *Strep. lactis*, but was considered to be impracticable on the large scale because of its cost.

METHOD OF PREPARATION

After incubation for 48 hours at 30°C of 150-litre quantities of the medium described, the acidity changed from pH 7·2 to about 4·4, with an activity of about 80 units per ml. At this stage much of the active substance accompanies the bacterial cells, but on acidification to below pH 3 it virtually all passes into the broth, from which it may be recovered as follows:

(1) Centrifuge, using a cream separator, after acidifying with 10 *N*.HCl to pH 2, discarding the bacterial cells.

(2) Adjust the centrifugate to pH 4·2–4·5 with 10 *N*.NaOH.

(3) Add 5% v/v of chloroform and 0·1% secondary octyl alcohol and stir the 150-litre bulk with a centrifugal pump to emulsify the chloroform in the medium (Sevag et al. 1938). Allow to settle and siphon off the supernatant inactive broth.

(4) Centrifuge the stable chloroform gel remaining (usually about 10 litres) at about 1500 r.p.m. for 10 min. to remove the residual broth and unemulsified chloroform. The volume is now about 5 litres.

TABLE I—INHIBITORY EFFECTS OF DIFFERENT STREPTOC[illegible] ON ONE ANOTHER

—			Test organisms *						
			Strep. lactis		Intermediate		*Strep. cremoris*		
			A	B	C	D	E	F	[illegible]
Nisin producers	*Strep. lactis*	A	..	0	0	0	320	320	[illegible]
		B	0	..	0	0	320	320	[illegible]
	Intermediate	C	0	0	..	0	320	320	[illegible]
		D	0	0	0	..	100	160	[illegible]
Diplococcin producers	*Strep. cremoris*	E	80	0	80	0	..	0	[illegible]
		F	160	0	160	0	0	..	[illegible]
		G	320	10	160	20	0	0	..

* Figures are dilutions at which inhibition just observable at [illegible] hours.

(5) Cool to about 4°C and add cold absolute alcohol. This dissolves the chloroform and precipitates the active substance. Alcohol is added until the precipitate sinks readily for removal by centrifugation.

(6) Dissolve the precipitate so recovered in *N*/20 HCl at 50°C. Remove the residual chloroform by blowing in hot air, with stirring. The volume is now about 15 litres with an activity of 500–1000 units per ml., the solids' content being reduced by 90–97%.

(7) Raise the pH of the acid solution to 2·5–3 with *N*.NaOH, add an equal volume of cold alcohol, and keep the bulk in the cold for 24 hours.

(8) Remove the inactive precipitate by centrifuging, and concentrate the alcoholic solution in vacuo at about 10°C to half its volume, maintaining the pH by additions of *N*.NaOH. Finally bring the pH to about 4 and keep the solution in the cold for a further 24 hours.

(9) Remove the active precipitate, wash it with neutral distilled water, dissolve in the smallest volume of *N*/100 HCl, and freeze-dry the solution.

This preparation contains no ash (except NaCl), has an activity of 1–2 million units per g., and is stable to boiling in acid solution. The dry powder is stable for months at least and is not hygroscopic. The yield is about 16–20 mg./l. of culture medium—i.e., about 20% of the possible.

EFFECT ON LEUCOCYTES AND RED CELLS

With the technique of Abraham et al. (1941) even the very impure preparations, with a nisin concentration of about 1/250, had no observable effect on leucocyte mobility and caused no hæmolysis of red cells.

RATE OF EXCRETION

It has not yet been possible to determine rates of excretion with the highly purified substance. With impure preparations it has been found that in the rabbit (2–3 kg.), after the intramuscular injection of 200,000 units, significant concentrations—i.e., 4 units per ml. —remain in the serum after six hours.

After intravenous injection of similar quantities the concentration declines more rapidly. After subcutaneous injection significant concentrations were maintained longer than when injections were made intramuscularly or intravenously, but the peaks were lower. Repeated subcutaneous injections led apparently to a build-up in the serum. In these experiments the concentration of inhibitory substance in the serum was determined by means of *Strep. pyogenes* (*Richards*). Active material was excreted in the urine of rabbits and guineapigs.

TOXICITY

With the impure substance the LD/50 observed in mice is very high—about 3·5 g./kg. of body-weight.

A total dose, spread over four weeks, of about 9 g./kg. of body-weight caused no observable macroscopic systemic effect in guineapigs.

Clinically the cases were divided into four groups as follows:

	Cases
Congenital syphilis	25
Early latent syphilis (known to have acquired primary or secondary syphilis within the previous five years)	33
Latent syphilis (duration unknown)	34
Late symptomatic syphilis	28

Of these 120 cases, 3 congenital, 5 early latent, 3 latent of unknown duration, and 3 late symptomatic cases had abnormal positive signs in the C.S.F. and were therefore regarded as having asymptomatic neurosyphilis also; 4 others with symptomatic neurosyphilis had abnormal cerebrospinal fluids.

Of 80 patients who had received previous treatment with arsenic and bismuth the subsequent administration of penicillin was followed by a favourable blood response in 45. The total dosage of penicillin was 2,400,000 units in 61 cases, and 4,000,000–4,800,000 units in 59 cases. There was no significant difference in the number of successes obtained in these two groups. Only 34 patients received consolidation treatment with arsenic and bismuth after the penicillin; 18 of these had received no treatment before penicillin, and 16 fell in the late symptomatic group and were selected on the basis of clinical severity; 12 of them were regarded as successes, while in 22 the serology was unchanged. A high serological titre was found in 28 of them when the penicillin was given, and only 8 of these showed serological improvement in spite of the combined treatment.

CONGENITAL SYPHILIS

The 25 patients in this group had a mean age of 26·5 years, and previous treatment had already been given to 21 of them to an average of 3·18 courses of arsenic and bismuth. At some time 7 had had interstitial keratitis, 4 Clutton's joints, 3 gummata, 2 neurological signs, and 8 no signs other than facial or other stigmata; 1 was referred on the grounds of family history.

As a result of previous treatment 7 had low titres when penicillin was begun, and 5 of these reached seronegativity in six months, though 2 later relapsed. One of them had a clinical relapse of interstitial keratitis at six months while the serum was still negative, though it later became weakly positive. In 2 instances the improvement was aided by adjuvant treatment.

One other patient, who had received previous treatment but was strongly positive when the penicillin was administered, had previously had a fluctuating titre, and seronegativity was reached here without other measures. Of the remaining 17, 13 had had persistent high titres, and none showed any further improvement with penicillin. The remaining 4, who had had no previous treatment and had high titres, were not improved.

Only 6 of the 25 received any treatment after the penicillin and 2 of these were successes. Total improvement for the group: 6 out of 25 (24%).

EARLY LATENT SYPHILIS

The 33 patients with early latent syphilis had a mean age of 28·3 years, and *all* had had previous treatment to an average of 3·35 courses of arsenic and bismuth for primary or secondary syphilis known to have been contracted on an average thirty months previously (extremes: nine months and five years). In all cases the serology was positive when penicillin was given; so they were in effect cases of either sero-relapse or sero-resistance to an early infection. However, 11 had low titres as the result of previous treatment, and 22 had high titres, but 15 of these had at some time reached seronegativity and were therefore now serological relapses, and 7 had been persistently seropositive throughout.

Of the 11 with low titres, 9 had reached seronegativity at six months, but at nine months 2 had relapsed, and at twelve months 3 more. None had after-treatment before the relapse. Of the 7 with fixed titres only 3 had improved at six months, but of the 15 who had at one time been seronegative no less than 14 became seronegative again by six months after the penicillin, and there were no later relapses. Of the 26 cases showing improvement only 3 received additional treatment after the penicillin.

The duration of the syphilitic infection being much lower for this group than for the others, the improvement-rate is considerably higher. It is particularly notable that the known existence of a fluctuating titre is a good prognostic sign of the expected response to penicillin, though it is probable that further metallotherapy would have produced a similar result. Total improvement for the group: 26 out of 33 (78·8%).

LATENT SYPHILIS OF UNKNOWN DURATION

The group with latent syphilis of unknown duration comprised 34 patients with an average age of 30·6 years. All cases were asymptomatic, the positive serology being discovered in 10 at final tests of cure for gonorrhœa or urethritis; in 3 during attacks of epididymitis; in 3 during polyarthritis; in 2 in donors for blood-transfusion; in 4 during investigation for quasi-venereal complaints; in 4 during investigation of sore throat, enlarged glands, or headache; in 2 during investigation of indefinite skin complaints; and in 6 the reason for discovery was unknown.

Previous treatment had been given to 16 to an average of 3·1 courses of arsenic and bismuth. As a result of previous therapy 8 had an initially low titre; in these, 5 successes were obtained at six months, but 2 of them relapsed at nine months. Of 26 with initially high titres 2 had previously shown fluctuating titres, and both of these responded, whereas of 6 showing known fixed titres only one responded. The remaining 18 were previously untreated, and 8 had reached or approximated to seronegativity by six months. In the whole group after-treatment was given only to 9, and 4 of them were among the successes. Total improvement for the group: 16 out of 34 (47%).

LATE SYMPTOMATIC SYPHILIS

The 28 patients with late symptomatic syphilis had an average age of 35 years; 15 had gummata or late cutaneous syphilis, 3 leukoplakia, 3 cardiovascular syphilis, 2 ocular syphilis, and 5 symptomatic neurosyphilis. Of the gummata 4 were testicular: 1 diagnosed by biopsy, and 3 only after removal of the affected testicle before the patient was sent to the venereal-diseases clinic.

Previous treatment had been given to 10 patients, to an average of 3·6 courses, and as a result 5 had initially a low titre, and there was improvement to seronegativity at six months in 4 (1 of whom had received after-treatment). Of the 23 with high titres, 5 had had previous treatment without response, and only 1 showed further improvement with penicillin at six months and 1 at nine. Of the remaining 18 untreated cases, only 3 improved at six months, but 2 more had improved by nine months. After-treatment was given to 16, with only 3 successes. Total improvement for the group at six months: 8 out of 28 (28·6%).

ABNORMAL CEREBROSPINAL FLUID

In 18 cases the C.S.F. was abnormal before treatment; 15 of these had a further check after six months, of which 9 were much improved, 1 was slightly improved, 4 were unchanged, and 1 was worse.

Of the 18 cases, 3 were congenital syphilis, 1 being associated with an ocular palsy and 2 with interstitial keratitis. All had after-treatment, and previous treatment had been given to 2. In 2 the blood titres were initially low, and in 1 high. The high titre remained occasional microscopic needles in a mass of amorphous matter; but, when the wet amorphous precipitate obtained in this way was dissolved in an equal volume of absolute ethanol and precipitated therefrom by slow cooling, the nisin appeared in the form of long filaments. Subsequent preparations gave slightly larger crystalline needles, of which an example is shown in the accompanying photomicrograph. This particular preparation, when dissolved in N/20 hydrochloric acid, gave a solution containing 800,000–1,600,000 units per ml. and an organic dry weight of 16 mg. per ml., giving for the dry material an activity of 50–100 million units per g.

Thanks are due to Messrs. Benger's Ltd. for invaluable help in the preparation of crude active material, and to Mr. N. J. Gruber for photomicrography.

EFFECT OF PENICILLIN ON SEROLOGY OF LATE AND LATENT SYPHILIS

A STUDY OF 120 CASES FOLLOWED FOR SIX MONTHS OR MORE

R. R. WILLCOX
M.B. Lond.
ASSISTANT, V.D. DEPARTMENT, ST. MARY'S HOSPITAL, LONDON; FORMERLY ADVISER IN VENEREOLOGY TO THE WAR OFFICE

IT is well recognised that in late and latent syphilis serological reversal is not tantamount to a cure, and that, when such reversal has been achieved, the later complications of syphilis may still ensue.

Jordon and Dolce (1946), who described 169 cases of latent syphilis treated with various degrees of completeness with arsenic and bismuth and followed up ten years or more, had 2 patients both of whom developed syphilitic aortitis three and nine years after they had become seronegative. In the present series, where the period of observation was very much shorter, there was one instance of a relapse of active interstitial keratitis after seronegativity had been reached. However, the serological titre is a yardstick, and sometimes the only yardstick, by which progress may be measured, and a change to seronegativity is one of the results to be desired as an outcome of successful treatment. In the large series described by Jordon and Dolce *permanent* seronegativity was reached in about 40% of cases of latent syphilis, and it was suggested that, so far as the development of complications was concerned, a consistently strong titre was a bad, and a fluctuating one a good, prognostic sign.

In preliminary reports on the action of penicillin in late and latent syphilis Stokes et al. (1944) suggested that the serological principles applicable to arsenic and bismuth were applicable to penicillin also, and that some reduction in serological titre was usually obtained with penicillin, which reduction was greater in cases showing a higher titre than in cases showing a low one, and that such a decline in titre took place in 50–60% of cases treated.

Later, presenting an interim report of two years' work at a National Research Council meeting in Washington on Feb. 6, 1946, Stokes described 197 cases of neurosyphilis followed up 120 days or more, and noted that the good effects of penicillin on the findings in the cerebrospinal fluid (C.S.F.) were not always accompanied by a similar improvement in the blood—in only 31% was there similar improvement in both. It almost seemed, he added, as if a different mechanism was involved in the responses of the blood and C.S.F., and that, within the limits of the period of observation, the blood findings had little relation to symptoms and C.S.F. findings. Little information was forthcoming at this conference about the effect of penicillin in either latent or cardiovascular syphilis, though it was resolved to make a widespread investigation into its effects in latent syphilis.

Dexter and Tucker (1946) described the effects of penicillin in 19 cases of gummatous syphilis with a strongly positive serological titre. There was a general fall up to three months, which gradually came to a level at a year, though no case became seronegative.

PRESENT INVESTIGATION

The present cases were all military personnel with late syphilis, both symptomatic and latent, treated with penicillin at an Army military hospital. Most had received previous treatment with arsenic and bismuth, which, though it confuses the analysis, makes it possible to compare the results obtained with these drugs and those obtained with penicillin later. All cases were seropositive when penicillin was given. Commercial penicillin was used in total dosage schedules of 2·4, 4·0, and 4·8 million units in aqueous solution in three-hourly round-the-clock injections of 40,000 units. About two-thirds received American brands, and a third British penicillins. Some of these penicillins may have contained up to 30–40% of penicillin K, but their exact contents are unknown. After-treatment with arsenic and bismuth was given to some patients, usually those who had received no previous treatment; and, though this is a confusing factor in the few successes achieved with the combined treatment, it is assumed that a failure with penicillin plus arsenic and bismuth may be safely regarded as a failure with penicillin alone.

About 150 cases of late and latent syphilis were treated with penicillin before April, 1946, and these formed the subject of a brief announcement in a discussion at the Medical Society for the Study of Venereal Diseases in July, 1946. Of these cases, 120 were followed up six months or more and are selected for this study, 81 of them were followed up nine months, and 56 a year or more. The longest time that any patient was under observation was two years, the average being eleven months. A better follow-up was impossible, because this investigation was carried out in the teeth of demobilisation. A concerted effort was made to trace the patients into civilian life; but, judged on the relation of work done to results achieved, this was not very profitable. However, in consequence of some 350 letters, about 60 patients were traced to other treatment centres.

Before penicillin was administered, all patients had a complete clinical and C.S.F. examination. The penicillin schedules have been described; but, where there were clinical signs of late symptomatic syphilis or a positive C.S.F., the initial dose of penicillin was only 10,000 units, which was increased to the maximum of 40,000 units within thirty-six hours. No serious complications developed during treatment, apart from a few cases of urticaria. The subsequent régime of surveillance consisted of serological tests once a month for six months, when the C.S.F. was again examined. After this, bloods were examined quarterly for a year, and then six-monthly for a further year, at the end of which time the C.S.F. was due to be examined again (none of the 120 patients has yet reached this final stage). The serological tests consisted of a qualitative Wassermann and a quantitative Kahn; but, when seronegativity had already been reached, a standard Kahn was substituted for the quantitative test.

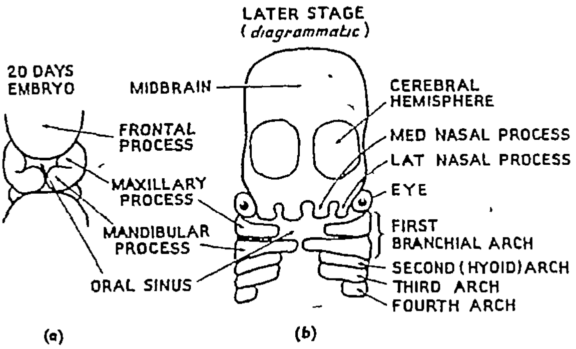

Fig. 1—Embryological development of jaws: (*a*) at 20 days; (*b*) later. (After Keibel and Mall 1910.)

weight of the body on the vertex, the pressure of the sternal region in contact with the mandible might force the jaws together; and, if the lower is united and the upper is not, the lower jaw might prevent union of the horizontal plates, causing cleft palate but allowing normal union of the alveolar ridge. This hypothesis explains the backward displacement of the tongue and its small size, though only one of the two cases described below showed these characters, and not all cases show cleft palate (Lapage 1937).

At 8–10 weeks of fœtal life the two lips project about equally, but at 10–12 weeks the upper lip and upper jaw grow more rapidly, with the result that at 4–5 months there is a considerable projection of the upper jaw (fig. 2). This difference is gradually overcome between 6 and 9 months by a stronger growth of the lower lip and mandible, and Keibel and Mall (1910) have suggested that the early fœtal arrangement may persist by a kind of inhibition of the latter process. Lanstrup (1925) declared that the process was most likely one of simple arrest of development, and an impressive series of 50 cases collected by Pfaff (1913) clearly showed that there was often some hereditary element, which in one case he traced through several generations. In the case reported by Lapage (1937) there was a family history of two previous babies dying because their lungs were never expanded, perhaps because of micrognathia and glossoptosis.

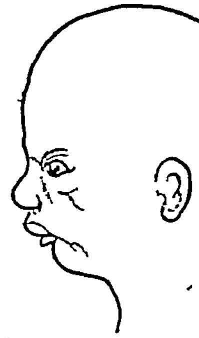

Fig. 2—Projecting upper lip and receding chin in fœtus at about 4th month.

Experiments on amniota have shown that bands or a deficiency in amniotic fluid can cause many deformities, and similar maldevelopment can be seen in the brachygnathia of the pekinese and pug-dog, while the "hog jaw" of sheep is another common example.

It appears reasonable to suppose that all these factors can operate to cause deformity; perhaps those cases with cleft palate are due to backward and upward pressure on tongue and lower jaw in the early stages, whereas pressure at 4–5 months could explain the micrognathia in cases without cleft palate.

CASE-RECORDS

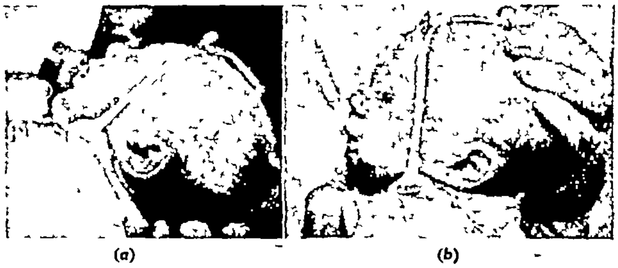
Case 1.—No hereditary factor was found; both parents were normal, and the child was the first born after eight years of marriage. Birth weight was 6 lb. 11 oz., and the child was admitted at 22 days, weighing 5 lb. $15^{1}/_{2}$ oz., with a history of difficulty in feeding, with frequent dyspnœa and cyanosis due to respiratory obstruction.

She was small and greyish, going blue at times; the mandible was very poorly developed, but the most striking feature was the respiratory obstruction. On inspiration there was regression of the lower jaw, with indrawing of the suprasternal region and intercostal spaces. No breath was taken with several such efforts, until at the sixth or seventh attempt a noisy grunting inspiration was heard. A midline cleft in the soft palate and a large tongue could be seen, the latter closing off the airway completely when the child was lying on its back. When the angles of the jaw were held forward, respiration was normal.

The baby sucked heartily but with little effect, and was fed by pipette for several days. Respiration was fairly satisfactory when she lay on her side or face, with the foot of the cot raised, but she was often found distressed and cyanosed, because she had contrived to move to the supine position.

A padded wire splint was fixed with tapes so that there was a constant pressure holding the mandible forwards (fig. 3). There was no soreness of jaw and head from the pressure of pads and tapes. On the tenth day after admission weight had risen to 6 lb. $4^{3}/_{4}$ oz., but the soldered splint was broken; the respiratory rate rose from 32 to 48 per min. over the next two days, and signs of bronchopneumonia developed. A second splint was made from one piece of tempered steel wire, and slow recovery ensued on sulphathiazole therapy.

A month after admission the profile had already made some improvement, but there was still a noticeable difference when the splint was worn (compare figs. 3 and 4). Progress was slow but maintained, and 14 weeks after admission the child could breathe and feed without any help from the splint. She began to speak at one year, when she weighed 23 lb. 14 oz., the defect in the palate was closed by operation, and she now appears normal.



(*a*) (*b*)

Fig. 3—Case 1, with padded wire splint in position: (*a*) feeding (*b*) at rest.

Case 2.—No hereditary factor was found. There was one sibling, reported normal. Birth weight was 7 lb. 10 oz., and the child was admitted at 10 days, weighing 7 lb. 6 oz., with a history of an abnormal mouth, an odd cry, and not taking feeds except by œsophageal tube.

He was hypotonic, cyanosed, and thin. The mandible was very poorly developed. The tongue was very small and fell back into the cleft in the soft palate.

When the baby was in the supine position the respiratory excursions were astonishing. The sternum was raised like the keel of a ship, and there was marked recession of the lower ribs. Five of these respiratory efforts failed to draw air into the lungs, but at the sixth attempt the air entry was moderately good. If the baby was placed on his side or nursed upright the respiration was much improved; dyspnœa was also relieved by pressing forward the angles of the jaw.

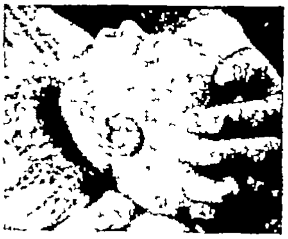


Fig. 4—Case 1 with splint removed. Compare fig. 3.

A splint was more difficult to adjust than in case 1, partly because of pressure sores at the angles of the jaw. Eventually the splint used for case 1 was applied for increasingly long periods of the day.

All food taken by normal bottle or spoon was regurgitated through the nose. The baby appeared to suck well, but really took very little. Four-hourly œsophageal feeds were therefore given. His stools always consisted of undigested food, containing much mucus and fatty curds. Lactic-acid milk, though digested best, would not pass through the unchanged though the C.S.F. became worse; 1 of the 2 low titres improved in both blood and C.S.F., though the blood later relapsed: and in the other there was a pronounced change for the better in the blood but only slight improvement in the C.S.F.

There were 5 cases of latent syphilis of known recent duration; 3 with high and 2 with low blood titres. All had had previous treatment, and after-treatment was given to 2. Improvement in blood titre was noted in all 5; and of the 4 whose C.S.F. was examined at six months, 2 were much improved and 2 showed no change.

There were 3 cases of latent syphilis of unknown duration, and none had had previous treatment, but 1 had after-therapy. In 2 cases the C.S.F. was examined after six months, 1 showing much improvement and 1 no change: but both still showed a high titre in the blood.

There were 7 *cases of late symptomatic syphilis*: 4 were pure neurosyphilis, whereas 2 with gummata and 1 with aortitis had asymptomatic neurosyphilis. The blood titre was low in 1 but high in the rest. Of 6 cases in which the C.S.F. was re-examined at six months, 5 showed much improvement and 1 was unchanged. In only 1 was there improvement in the blood in the same time. One patient had had previous treatment, and all had further therapy after the penicillin.

Thus, in the 18 patients with a positive C.S.F., 13 had a high and 5 a low serological titre when the penicillin was given. Previous treatment had been given to 8 and after-treatment to 13. There was improvement in both blood and C.S.F. in 5 cases; improvement in the C.S.F. but not in the blood in 5; improvement in the blood but not in the C.S.F. in 2; no change in blood and C.S.F. in 2; and in 1 the blood titre remained stationary while the C.S.F. became worse. In 3 cases the C.S.F. was not re-examined during the period of this study.

Thus the findings in the blood and in the C.S.F. were not concomitant. Of the 9 cases showing much improvement of C.S.F. only 3 showed similar improvement of the blood.

SEROLOGICAL STABILITY

The serological results can be arranged in four groups:

(1) Low declining titre (due to previous treatment).

(2) High fluctuating titre (known to have reached seronegativity during previous treatment).

(3) High fixed titre (completely resistant to previous treatment).

(4) High titre, stability unknown (cases not treated previously).

This arrangement discloses wide differences in the response of the blood serology to penicillin. In the following tables improvement is regarded as a reversal from a low titre to seronegativity, or from a high titre to seronegativity or near-seronegativity, which means that either the Wassermann or the Kahn was negative, or that both were only plus-minus reactions.

	No. of cases	*Improvement*
(1) *Low declining titre:*		
Congenital	7	5
Early latent	11	9
Unknown latent	8	5
Symptomatic	5	4
	31	23 (*74·2%*)

(5 later relapsed at nine months, and 4 at a year)

	No. of cases	*Improvement*
(2) *High fluctuating titre:*		
Congenital	1	1
Early latent	15	14
Unknown latent	2	2
Symptomatic	0	0
	18	17 (*94·4%*)

(No relapses)

	No. of cases	*Improvement*
(3) *High fixed titre:*		
Congenital	13	0
Early latent	7	3
Unknown latent	6	1
Symptomatic	5	1
	31	5 (*16·1%*)

No relapses; 2 did not show any improvement until the ninth month)

	No. of cases	*Improvement*
(4) *High titre, stability unknown:*		
Congenital	4	0
Early latent	0	0
Unknown latent	18	8
Symptomatic	18	3
	40	11 (*27·5%*)

(No relapses; 2 later improved at nine months)

It is readily seen that groups 1 and 2, both of which had known fluctuating titres, brought a large measure of success, whereas group 3, which had previously failed, did not show much evidence of further improvement. Group 4, containing a potential mixture of all the previous groups, had a mean of successes.

SUMMARY

The effects of penicillin on the serology of 120 patients with late or latent syphilis followed up for six months or more are described.

Only 34 received any after-treatment and these accounted for only 12 of the 56 successes obtained. Previous treatment with arsenic and bismuth had been given to 80 patients and served as a gauge of the likely response to further antisyphilitic measures.

Improvement was greatest in latent syphilis of known recent origin and least in late symptomatic and congenital syphilis.

Cases with an initially low titre did much better at six months than those where the titre was high. However, later observation showed no further improvement but an appreciable number of relapses in those with a low titre, whereas some of those with initially a high titre began to improve up to nine months, or continued to improve up to a year, with no such incidence of relapse.

Those cases where the titre was fixed to arsenic and bismuth did much worse than those where the titre was known to have been fluctuating.

Previously untreated cases fell midway between these two groups.

There was no concomitance between the response in the C.S.F. and the serological titre.

MICROGNATHIA

REPORT OF TWO CASES

A. M. SWEET B.M. Oxfd
MARGARET KEMSLEY M.B. Lond.

LATE HOUSE-PHYSICIANS, RADCLIFFE INFIRMARY, RYCOTE PARK EXTENSION

POOR development of the mandible, with regression of the lower jaw, is a relatively common congenital abnormality, is often associated with cleft palate, and leads to difficulties in respiration and feeding and death from athrepsia.

In the third week of intra-uterine life the basic design of the face consists of a median frontal process and of separate paired maxillary and mandibular processes formed from the first branchial arch (fig. 1). Later development is more complex, but the median and lateral nasal processes develop and fuse together, and with the maxillary processes form nose, palate, and upper jaw, the two mandibular processes fusing to form the lower jaw. Formation of the face thus involves the orderly conduct of several pairs of primordia growing normally and fusing regularly and precisely. (See Keibel and Mall 1910.)

Davis and Dunn (1933) suggest the following explanation of micrognathia. The mandible is formed earlier than the upper jaw, and acts as the matrix on which the upper jaw is formed. In the fœtus in utero, with the

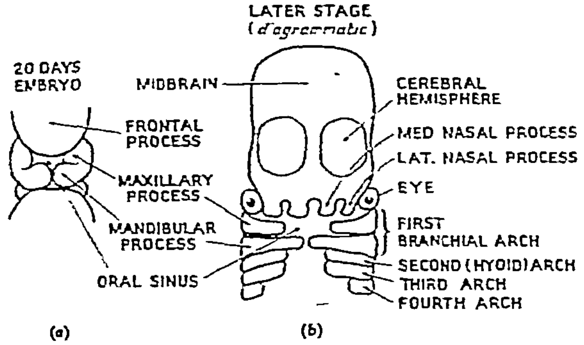

Fig. 1—Embryological development of jaws: (a) at 20 days; (b) later. (After Keibel and Mall 1910.)

weight of the body on the vertex, the pressure of the sternal region in contact with the mandible might force the jaws together; and, if the lower is united and the upper is not, the lower jaw might prevent union of the horizontal plates, causing cleft palate but allowing normal union of the alveolar ridge. This hypothesis explains the backward displacement of the tongue and its small size, though only one of the two cases described below showed these characters, and not all cases show cleft palate (Lapage 1937).

At 8–10 weeks of fœtal life the two lips project about equally, but at 10–12 weeks the upper lip and upper jaw grow more rapidly, with the result that at 4–5 months there is a considerable projection of the upper jaw (fig. 2). This difference is gradually overcome between 6 and 9 months by a stronger growth of the lower lip and mandible, and Keibel and Mall (1910) have suggested that the early fœtal arrangement may persist by a kind of inhibition of the latter process. Lanstrup (1925) declared that the process was most likely one of simple arrest of development, and an impressive series of 50 cases collected by Pfaff (1913) clearly showed that there was often some hereditary element, which in one case he traced through several generations. In the case reported by Lapage (1937) there was a family history of two previous babies dying because their lungs were never expanded, perhaps because of micrognathia and glossoptosis.

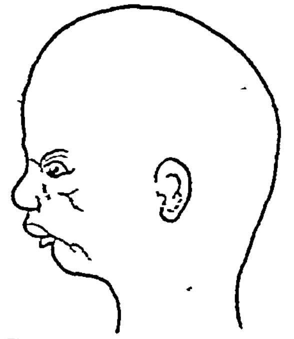

Fig. 2—Projecting upper lip and receding chin in fœtus at about 4th month.

Experiments on amniota have shown that bands or a deficiency in amniotic fluid can cause many deformities, and similar maldevelopment can be seen in the brachygnathia of the pekinese and pug-dog, while the "hog jaw" of sheep is another common example.

It appears reasonable to suppose that all these factors can operate to cause deformity; perhaps those cases with cleft palate are due to backward and upward pressure on tongue and lower jaw in the early stages, whereas pressure at 4–5 months could explain the micrognathia in cases without cleft palate.

CASE-RECORDS

Case 1.—No hereditary factor was found; both parents were normal, and the child was the first born after eight years of marriage. Birth weight was 6 lb. 11 oz., and the child was admitted at 22 days, weighing 5 lb. 15½ oz., with a history of difficulty in feeding, with frequent dyspnœa and cyanosis due to respiratory obstruction.

She was small and greyish, going blue at times; the mandible was very poorly developed, but the most striking feature was the respiratory obstruction. On inspiration there was regression of the lower jaw, with indrawing of the suprasternal region and intercostal spaces. No breath was taken with several such efforts, until at the sixth or seventh attempt a noisy grunting inspiration was heard. A midline cleft in the soft palate and a large tongue could be seen, the latter closing off the airway completely when the child was lying on its back. When the angles of the jaw were held forward, respiration was normal.

The baby sucked heartily but with little effect, and was fed by pipette for several days. Respiration was fairly satisfactory when she lay on her side or face, with the foot of the cot raised, but she was often found distressed and cyanosed, because she had contrived to move to the supine position.

A padded wire splint was fixed with tapes so that there was a constant pressure holding the mandible forwards (fig. 3). There was no soreness of jaw and head from the pressure of pads and tapes. On the tenth day after admission weight had risen to 6 lb. 4¾ oz., but the soldered splint was broken; the respiratory rate rose from 32 to 48 per min. over the next two days, and signs of bronchopneumonia developed. A second splint was made from one piece of tempered steel wire, and slow recovery ensued on sulphathiazole therapy.

A month after admission the profile had already made some improvement, but there was still a noticeable difference when the splint was worn (compare figs. 3 and 4). Progress was slow but maintained, and 14 weeks after admission the child could breathe and feed without any help from the splint. She began to speak at one year, when she weighed 23 lb. 14 oz., the defect in the palate was closed by operation, and she now appears normal.

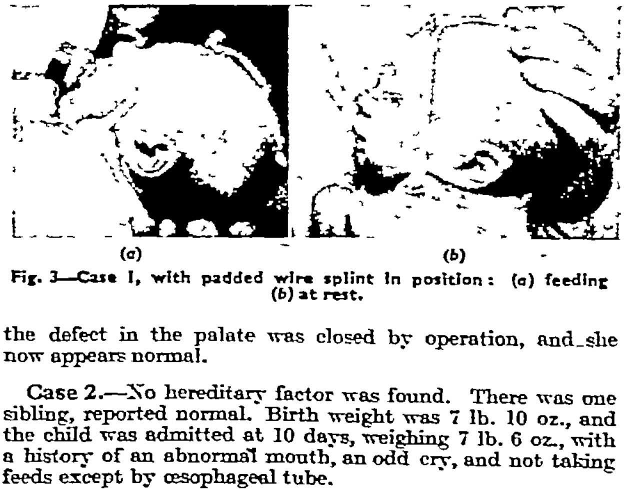

Fig. 3—Case 1, with padded wire splint in position: (a) feeding (b) at rest.

Case 2.—No hereditary factor was found. There was one sibling, reported normal. Birth weight was 7 lb. 10 oz., and the child was admitted at 10 days, weighing 7 lb. 6 oz., with a history of an abnormal mouth, an odd cry, and not taking feeds except by œsophageal tube.

He was hypotonic, cyanosed, and thin. The mandible was very poorly developed. The tongue was very small and fell back into the cleft in the soft palate.

When the baby was in the supine position the respiratory excursions were astonishing. The sternum was raised like the keel of a ship, and there was marked recession of the lower ribs. Five of these respiratory efforts failed to draw air into the lungs, but at the sixth attempt the air entry was moderately good. If the baby was placed on his side or nursed upright the respiration was much improved; dyspnœa was also relieved by pressing forward the angles of the jaw.

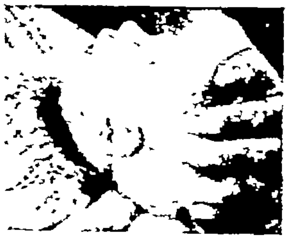

Fig. 4—Case 1 with splint removed. Compare fig. 3.

A splint was more difficult to adjust than in case 1, partly because of pressure sores at the angles of the jaw. Eventually the splint used for case 1 was applied for increasingly long periods of the day.

All food taken by normal bottle or spoon was regurgitated through the nose. The baby appeared to suck well, but really took very little. Four-hourly œsophageal feeds were therefore given. His stools always consisted of undigested food, containing much mucus and fatty curds. Lactic-acid milk, though digested best, would not pass through the œsophageal tube without curdling. The only food the baby could digest was Nestlé's milk. He became dehydrated and had to have subcutaneous saline by drip and injection.

When he was nearly 4 weeks old a special teat was devised. A fine rubber catheter was passed through a feeding-bottle and protruded $^3/_4$ in. beyond the end of the teat (fig. 5) and so projected the food over the backwardly displaced tongue and beyond the cleft in the palate.

As the baby's powers of sucking developed, his digestion and the tone of the masseter, temporal, and pterygoid muscles improved. At 9 weeks he could suck from an ordinary teat. At 6 $^1/_2$ weeks he had a strangulated inguinal hernia, which was reduced, under local anæsthesia, by Mr. E. Moloney at the Radcliffe Infirmary. The progress of the baby was in no way disturbed:

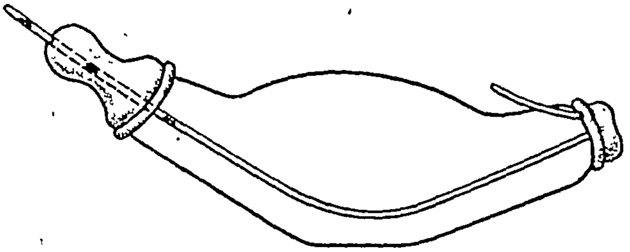

Fig. 5—Feeding-bottle, with rubber catheter projecting through teat, devised for feeding case 2.

Age		*Weight*
4 weeks	..	7 lb. 2 oz. (before using special teat).
8 $^1/_2$,,	..	8 lb. 4 oz. (after using special teat).
12 ,,	..	8 lb. 15 oz. (discharged).

Progress since has been well maintained.

DISCUSSION

Case 1 differs in several respects from the usual micrognathia; the tongue was large, whereas usually it is much smaller than normal according to Davis and Dunn (1933), who describe how in their case the cleft palate alleviated the dyspnœa to some extent; but in case 1 reported here the tongue dropped backwards and upwards and caused complete respiratory obstruction if the child lay on her back.

At first sight it appears that, if the tongue could be anchored to the floor of the mouth, the respiration would be adequate, but such an operation always leads to bronchopneumonia. Postural feeding with the child lying on its side or upright has often been sufficient, and Dr. Chodak Gregory and Dr. Lilian Tracey (1943) nursed their cases in the prone position, the former allowing the head to project over a pillow, the latter using 'Elastoplast' to maintain position. Davis and Dunn (1933) used in their case an adjustable lip guard, so that the baby was forced to bring its lower jaw forward to feed, with gradual and permanent improvement in profile. Eley and Farber (1930) describe a splint which they used, but Lapage (1937) found the appliance unsuccessful in his case.

CONCLUSION

Micrognathia seems to be best treated by postural methods of feeding, using modified teats when cleft palate makes this necessary. If the tongue causes much respiratory obstruction the child should be kept prone or a light splint should be used to hold the mandible forward.

We should like to thank Dr. V. Smallpeice for her encouragement and advice, and Sister Bromwich and the nurses for their efficiency and skill.

MANAGEMENT OF A PERMANENT COLOSTOMY

STUDY OF 100 PATIENTS AT HOME

CUTHBERT E. DUKES
M.D. Edin., M.Sc. Lond., D.P.H.
PATHOLOGIST, ST. MARK'S HOSPITAL, LONDON

A PERSON with a permanent colostomy has to make many new adaptations to life. These can seldom be discussed fully when the necessity for the operation is first explained to a patient, because the whole outlook is dominated by the gravity of the urgent symptoms which make the colostomy necessary. It happens therefore very often that a patient "wakes up," so to speak, to find himself with a colostomy and turns to his doctor later for advice about its management.

One of the first points which have to be settled is whether the colostomy patient should adopt the plan of a daily washout or should be trained in natural colostomy evacuations. On this question widely different views were expressed at a discussion of the section of proctology of the Royal Society of Medicine (1945), when some surgeons advocated regular daily washouts whereas others condemned them as unnecessary or even dangerous. There was a difference of opinion also on the degree of incapacity and inconvenience caused by a colostomy, and the nature of the work ex-patients might undertake. A few weeks earlier a leading article in THE LANCET (1945) very properly observed: "The surgeon who gives a patient an artificial anus should always find time to teach him how to manage it. Often such patients are sent home with but little preliminary practice and instruction, and the misery in the household while experience is being gained may then be intense."

I thought some of the points in dispute might be settled by visiting experienced colostomy patients in their own homes, so set out to visit 100 old patients from St. Mark's Hospital, all of whom had undergone excision of the rectum for cancer, being left with a permanent colostomy. The visits were made between September, 1945, and April, 1946. Most of the homes visited were in the east and north-east of London, though some visits were also paid in south London and some in the Home Counties and the Midlands. Nearly all the patients visited belonged to the hospital class and were either insured persons or in receipt of public assistance. They formed a fair sample of the outpatient class, but the conclusion to be drawn from this survey would not apply without qualification to other social classes.

General information was collected about state of health, capacity for work, social conditions, diet, mental and emotional effect of colostomy, &c., but the main object of the visits was to find out whether regular daily washouts were undertaken, the frequency of action of the colostomy, and the manner of carrying out dressings. About three-quarters of the patients were seen personally; in the other cases interviews with relations or friends supplied the information required.

GENERAL HEALTH

Nearly all the patients visited were in good health. Only 2 were bedridden, and 8 or 9 were semi-invalids. Most of the patients were over sixty years of age, and their general health seemed as good as one would expect to find in any similar group of the same age and social class. Several of the patients had been living a colostomy life for many years. About half had had the colostomy performed more than five years previously. Of the 100 patients, 10 had had their colostomy more than twenty years previously, and 2 of them more than thirty years, the longest being thirty-five years.

As examples of the way in which patients can adapt themselves to a colostomy life, brief reference may be made to a man who had had a colostomy for thirty-five years and a woman who had one for thirty-two years.

Case 1.—A man, now sixty-eight, had a colostomy and perineal excision done by the late Mr. Swinford Edwards in 1911, when the patient was only thirty-three years old. He has remained in good health since the operation, and for more than thirty years continued to work in a boot shop, only retiring when his business premises were demolished by a flying-bomb. He gave up daily washouts when the air-raids began in the first world war, about 1915. Therefore it is about thirty years since he ceased regular washouts; yet he has no trouble with evacuations, which take place naturally twice a day and sometimes at night.

Case 2.—The oldest woman patient visited was aged eighty-three. She was operated on by Mr. Lockhart Mummery more than thirty years ago, and for the greater part of this time has been living alone in a single room attending to all her own requirements. She was taught to give herself a washout when in hospital and has continued to do so regularly ever since without questioning its necessity.

These then are two examples, one of whom has followed the washout technique for thirty years while the other has dispensed with it for a similar time.

OCCUPATIONS

Nearly all the patients visited could do some sort of work, usually household duties, hobbies, or light work. Only 5 declared they could do nothing. Three-quarters of the men did something to earn their living. The following are some of the occupations recorded: musical instrument maker, wood-turner, tobacconist, optician, book-packet, taxi-driver, cabinet-maker, night-watchman, and clerical work of various kinds. Many also worked at gardening or allotments or repairing bomb damage. It may be an encouragement to other patients to mention a few details about some cases.

Case 3.—This man acted as caretaker at a council school. In spite of his colostomy he served as a local air-raid warden throughout the war and received a letter of commendation from the mayor and corporation. This is framed and hung on the wall above the enamel can from which he gives himself his daily washout.

Case 4 has kept an optician's shop for nine years. His colostomy works twice a day, night and morning, and is no trouble to him. He has never given himself a washout.

Case 5 acted as head postman in a country town for nine years until he retired at the age of sixty.

Case 6 worked as a district inspector on the railway for three years till he retired at the age of sixty-five. He then took up bowls, and now at sixty-eight is a local champion.

Case 7.—Perhaps the most remarkable story is that of a woman who was operated on eleven years ago for rectal cancer. During the war she wanted to work in a hospital as a nurse; but, thinking she would be rejected if it were known that she had a colostomy, she kept this a secret and did not confide it to anyone. She was accepted and served throughout the war at her local hospital. She often worked in wards where colostomy patients were being nursed and was able to give them useful advice. She found many were very despondent at the thought of the difficulties they would meet at home; so, when no-one was about, she sat down and gave these patients a little first-hand information. Her advice was much appreciated, and patients often remarked that they were surprised she knew so much about the subject. The fact of her own colostomy was never discovered.

IS A DAILY WASHOUT NECESSARY?

Until the last three or four years all patients at St. Mark's Hospital were taught to give themselves a daily washout and instructed to continue this at home, but more recently Gabriel (1945) has advised his patients not to wash themselves out, and some other surgeons have given similar advice.

About a third of the patients visited continued to give themselves a daily washout because they had been told to do so, and about two-thirds had either never washed out the colostomy or had given up the practice some years ago. There seemed to be no difference in the general health of those who did and those who did not wash out. Several patients who had been told to wash out the colostomy daily did so for some time after leaving hospital and abandoned the practice later without any deterioration in their health. Some of these said they resorted to a washout occasionally, but no patient who had been trained in natural colostomy evacuations adopted regular daily washouts after returning home.

The advantage of the daily washout is that if the patient has a satisfactory clearance in the morning there is less likelihood of accidents later in the day. Its disadvantages are that it takes a great deal of time and is apt to be messy, unless the patient has undisputed possession of the bathroom and lavatory for an hour or so each morning. Also the washout technique is not without risk, because the passage of the tube into the bowel has been known to cause perforation leading to fatal peritonitis.

Surgeons who recommend regular colostomy washouts should bear in mind that these are apt to be a nuisance to the patient, his family, and fellow residents. In many houses visited there was no bathroom, and often the single lavatory was used by more than one family. Some houses had no indoor sanitation at all. Conditions are of course different in the homes of patients of other social classes. Regular washouts may be necessary for special medical reasons in some cases, but for the ordinary hospital patient the abolition of the washout would be a merciful deliverance.

NATURAL COLOSTOMY EVACUATIONS

Patients trained to natural colostomy evacuations mostly find that the colostomy works of its own accord two or three times during the day and occasionally at night. Many learn to pass a motion through the colostomy each morning after breakfast and then are not troubled again for most of the day. There may be another smaller action in the afternoon or evening, but these secondary motions may also be made into regular habits.

The number of motions can largely be controlled by diet. As a rule fruit and vegetables have a laxative action and have to be restricted. The best diet for a colostomy patient is a moderately mixed one containing meat, fish, eggs, milk, bread, butter, and milk puddings, such as tapioca and semolina. Most vegetables and fruit have to be taken in moderation. Stewed fruit, such as apples, can usually be taken in small quantities. Raw apples should be very carefully chewed, oranges should be sucked, and all fruit with seeds or pips should be avoided.

It is easier to acquire a regular evacuation habit if the motion is solid, and a well-formed motion is certainly more easily dealt with than liquid material. The regular passage of a formed motion keeps the colostomy healthy and leads to better control of the evacuations. A tendency to constipation can generally be overcome by increasing the quantity of vegetables in the diet or by adding some stewed fruit. Laxative medicines should be avoided if possible; but, if they are really necessary, a small dose of emulsion of magnesia or of liquid paraffin will probably be most suitable. If the motions become too frequent, the effect of reducing vegetables and fruit should first be tried; if this does not cure the trouble, a teaspoonful of 'Normacol' or kaolin taken at night will help to form a bulky semi-solid stool.

BELTS

Colostomy patients need a belt during the day to support the abdomen and keep the dressings in position. Belts with a cup or a bag attached are unnecessary for most patients and may be harmful by encouraging prolapse. If more support is needed than is given by the belt alone, the best plan is to cut out a round piece of cardboard or celluloid about the size of a saucer and to wear this between the dressings and the colostomy belt. This may be a help to those who have heavy manual work to do or are troubled with a chronic cough. At night the colostomy belt may be discarded. All that need be worn at night is a wide crêpe binder or closely fitting wrapper which will keep the dressing in position.

COLOSTOMY DRESSINGS

The most suitable dressing is a pad of absorbent cellulose wadding about 6 inches square. Most patients find it best first to cover the colostomy opening with a small piece of linen or gauze smeared with soft paraffin or with a small piece of toilet paper, to prevent the cellulose wadding from sticking. The colostomy pads now used at St. Mark's Hospital are made of white absorbent cellulose wadding but have a backing of pink non-absorbent material which prevents any discharge absorbed by the wadding from staining the belt or clothing. Instead of this pink non-absorbent material a square piece of jaconet may be used, or simply a folded towel or a pad of cotton-wool. The advantage of cellulose wadding as a dressing is that it is very absorbent, relatively inexpensive, and can be disposed of in a lavatory if it is thoroughly broken up with a stick. Cotton-wool and gauze are more expensive and will block the drain if thrown into a water-closet. The cellulose wadding costs between *1s. 6d.* and *2s.* a pound, which should make between thirty and forty pads.

EMOTIONAL RESPONSE TO COLOSTOMY

It comes as a great shock to patients to realise that they must live with an artificial opening for the rest of their lives. The fact that this opening is in an unnatural place, and that they do not seem to have complete control over it, at first weighs heavily on their minds. Most patients have gloomy thoughts about it as they recover from the operation, and it would be a help to have a talk with someone of their own age and social class who has made a successful adaptation to colostomy life. Later they become reconciled to it. They find it is not so bad as they anticipated, and learn to make the best of what has to be.

On the whole, women manage their colostomies better than men do. Women also seem to become less "colostomy conscious." A man who has to go out and earn his living and mix with other people tends to become more apprehensive about the colostomy than does a woman whose duties are mostly in the house. Those trained to natural colostomy evacuations think less of the colostomy than those who give themselves a daily washout.

A patient who is to have a colostomy, whether a man or a woman, is best off if married and in possession of a home. It was very touching to hear how men with colostomies spoke of the help they had received from their wives, and wives from their husbands. Incidentally, a colostomy does not seem to be an inseparable barrier to sex life. Among the 100 colostomy patients visited, at least one man and one woman had married after their operations. Two women, married at the time of colostomy, subsequently became pregnant.

Though most hospital patients make a brave and successful adaptation to the disadvantages of a colostomy life, many are haunted by a secret anxiety about what will happen to them if they are taken ill. They wonder whether their relations and friends will be able to look after them, and are afraid lest the colostomy will be a barrier to their admission to a hospital or an almshouse. This survey has emphasised the special need for a convalescent home where patients can be initiated into the routine of a colostomy life, and for institutions willing to take bedridden colostomy patients during their last days.

SUMMARY

A survey of 100 colostomy patients of the hospital class, visited in their homes, has shown that many keep in good health, lead useful lives, and seem to be little handicapped by the colostomy.

Daily colostomy washouts are unnecessary for patients in good health.

Most patients of the hospital class are less inconvenienced by the colostomy if they are trained to natural colostomy evacuations and use the cellulose-wadding absorbent dressings recommended.

BRONCHOMEDIASTINAL TUBERCULOSIS

PROGNOSIS AND TREATMENT*

HARLEY STEVENS
M.B. Sydney, M.R.C.P., D.P.H.
MEDICAL SUPERINTENDENT, BERKS AND BUCKS JOINT SANATORIUM, PEPPARD COMMON, OXON

VASCULAR dissemination of tuberculosis, after the primary infection, is due to the fact that the disease remains active in mediastinal glands.

Of the children admitted to the sanatorium at Peppard in the last three years 25% exhibited fluctuant subcutaneous swellings of the neck, or dirty granulating scars, the result of incising similar lesions. All had well-defined primary complexes in the chest. Many tuberculous infections of cervical glands may be due to vascular dissemination; Pagel (1942) puts the proportion very high, minimising the tonsillar route. Vascular dissemination is often prolonged and massive. Krause (1924) said that tuberculosis was a conspicuous example of metastasising infection either from the lungs to the rest of the body, or vice versa.

Though tubercle bacilli introduced from without are conveyed to the lungs, the tracheobronchial glands may be regarded as the nidus of infection, and we live in danger from our own lymph-nodes.

A boy, aged 8 years, was admitted with extensive pulmonary tuberculosis, active caries of the left carpus, and scores of discrete cutaneous nodules, one of which showed typical giant-cell systems.

The bacilli, one imagines, came from a caseous tracheobronchial gland and eventually, reaching the skin capillaries, passed to the other tissues.

The proximity of mediastinal glands, through lymph channels, to the blood-stream and their very wide field of drainage make repeated bacillæmia from that source seem relatively easy and comprehensible. Girdlestone (1940) says:

> "Tuberculosis of a bone or joint is a metastatic focus and a proof of disease elsewhere which is active enough to give rise to a bacillæmia. In children it almost always comes from long-standing infection of the lymphatic glands, and this lymphatic infection, though often unsuspected, is the root of the disease. . . . The glandular disease was established long before its more disabling and evident metastasis brought the patient to diagnosis and treatment."

TUBERCULOUS ENDOBRONCHITIS

Sometimes tuberculosis of mediastinal glands declares itself as a frank cold abscess.

A young married woman first came under observation with a cough, husky voice, and copious purulent sputum containing tubercle bacilli. Radiograms of the chest were reported normal.

Nine months later, on her admission to hospital, radiography still did not show any pulmonary abnormality, but bronchoscopy revealed typical tuberculous granulation tissue obstructing the left main bronchus.

Tuberculous endobronchitis may be the necrotic superficial portion of a collar-stud abscess and, like a dirty scar in the neck exuding beads of pus, be maintained by fistulous track from a caseous gland. Terplan (1945), his studies of necropsy material, noted such fistulæ pening into the bronchi.

---

* Adapted from a paper read at a meeting of the Tuberculosis Association.

The incidence of tuberculous endobronchitis is nknown, as the secondary bronchi, particularly those pplying the segments most commonly involved in arenchymatous disease, are not readily seen in the ving. Perez (1944) reported endobronchitis in about third of 100 consecutive necropsies on patients dying f pulmonary tuberculosis.

Regional lymph-nodes drain each pulmonary segment s well as each lobe, and any one of them may be the site f caseous tuberculosis capable of forming a collar-stud bscess and discharging into its adjacent air passage. ellular reaction about such glands leads to partial ronchial occlusion, lymph stasis, segmental exudate, nd collapse. It may also lead to pleural effusions and robably is the cause of many, particularly in childhood, without bacillary invasion of the interpleural space. With recent methods of searching gastric contents, ositive findings in cases of pleural effusion are increasngly frequent, even though bacilli are not recoverable rom the pleural fluid.

There are three types of pulmonary disease in which caseating bronchomediastinal gland, with possible racheobronchitis, is a prominent feature:

(1) In children, in whom epituberculous reactions are nore apparent. By refined methods tubercle bacilli an be recovered at some time from a considerable roportion. Occasionally, if the nurses are on the watch, hildren with a persisting epituberculosis or established ronchiectasis may have a coughing spasm and produce ninute amounts of caseous material swarming with tubercle bacilli, but more often inoculation of the gastric contents into guineapigs gives a positive result. The bronchiectasis is probably secondary to tuberculous tracheobronchial adenitis in a very high proportion of cases.

(2) Adults with minimal radiological evidence of parenchymatous infiltration but with a positive sputum. Artificial pneumothorax performed in such a case does not lead to the disappearance of tubercle bacilli from the sputum.

An airman, aged 22, after two years in the R.A.F., during which time he had three small hæmorrhages, reported sick and was found to have a positive sputum with a very little infiltration in the upper lobe of the right lung.

A right artificial pneumothorax gave concentric collapse, and no adhesions were present at a later thoracoscopy. But his sputum still contained tubercle bacilli, and bronchoscopy showed tuberculous granulation tissue in the right bronchus, confirmed by biopsy.

Sanatoria are providing long-term treatment for many such cases. The scepticism of a few years ago about positive sputum without definite or demonstrable parenchymatous ulceration has its logical and demonstrable answer in caseating tracheobronchial lymph-nodes.

(3) Cases with ballooning cavities of one or both lungs in which every conceivable form of collapse therapy may be tried in vain.

A girl, aged 18, was admitted early in 1941 with a history of hæmoptysis after bathing in August, 1940. She is still with us five years later. Many methods of splinting, with adhesion section giving free concentric collapse, have been used more than once. Her condition remains substantially unchanged. She has an obstructive wheeze and copious positive sputum. There are granulations in the right upper-lobe bronchus, and large cavities in each lung.

On the other hand, Terplan's (1945) studies led him to the view that primary complexes might heal completely. At Peppard 10% of children under the age of 9 years, admitted with radiological evidence of calcified hilar nodes, do not show any reaction to intradermal tuberculin. It is very difficult to avoid the corollary that, if a positive reaction is obtained, there is, or was recently, active tuberculosis in mediastinal glands due to an extension of a former primary focus.

I do not ignore the intestinal route of primary infection with a regional postmesenteric gland complex, but recent figures tend to minimise its importance, and extension to the mediastinal glands in these cases is usual, with calcification of the abdominal lesions; moreover, the human type of tubercle bacillus is commonly present.

COLLAR-STUD ABSCESS

The collar-stud abscess of tuberculosis is not confined to peripheral, cervical, and tracheobronchial adenitis. Tuberculous ulceration of the bowel is another example. Infection of the lymphoid tissue outside the lumen is either the result of lymphatic return after vascular dissemination from a central gland focus, or is achieved by phagocytic scavenging of the mucosa and conveyance of bacilli into the underlying tissues. There they set up a caseating process in lymph-nodes, which finally involves the mucosal surface. Circumrectal suppuration surely has a similar origin, the collar-stud in that case tracking caudally and pointing under the skin round the anus. Disease of bone often presents a collar-stud condition or cold abscess, of which the psoas abscess is a typical example.

PROGNOSIS

If some of the many glands grouped round bronchi and trachea may be the site of active tuberculosis over a long period and the source of hæmatogenous dissemination, we have a starting-point for considering both prognosis and treatment.

The outlook for peripheral lesions depends on (1) elimination of the superficial part of an abscess as a source of toxæmia; (2) the control of the deep end of the collar-stud either by general measures, local splinting, or excision; (3) the encapsulation and continued quiescence of any deep gland focus responsible for vascular dissemination; and (4) the sum of heredity, environment, and the ego, which make up the pattern of the individual life.

Uncomplicated by persistent and obstructive regional adenitis, cavity closure in the lungs and sputum conversion may be relatively simple, either by general treatment alone or by general treatment and local splinting. In the presence of such adenitis, with or without ulcerative tracheobronchitis, collapse therapy is relatively futile; moreover, a source of hæmatogenous dissemination, the deep gland, may continue to shower the bloodstream and produce metastatic foci. In twenty years of medicine I can recall several adult deaths from tuberculous meningitis unassociated with open lung disease but associated at necropsy with evidence of very definite mediastinal abscess. Therefore some of the two or three cases one sees annually of adult tuberculous meningitis and limited pulmonary disease may derive the meningeal infection by vascular dissemination from the mediastinum.

There does appear to be some variation in the prognostic significance of the individual bacillæmic metastasis. With the possible exception of lupus, cutaneous and superficial eye conditions heal. Cervical adenitis commonly subsides. Lesions of bone and joint, though often tedious, have a good outlook with modern treatment. Circumrectal suppuration, if adequately dealt with, is not comparable in the seriousness of its outlook with disease of the reproductive organs; and definite ulceration of the urinary tract is often of grave significance in spite of the numbers we all know going about the world with one kidney apiece. Young and Davis (1926) declared with little qualification that, when the urinary tract became involved in their patients, the prognosis was bad, and most of them died. Tuberculous *peritonitis, like tuberculous pleurisy, presents great* variations in its course, and the associated lesions have a direct bearing on the outcome. If it is combined with pericardial effusion and later constriction, not uncommon in the second decade, the cardiac symptoms become prominent. In two such recent cases occasional positive sputum reports were received, though no pulmonary cavities were evident, and fistulæ from caseous tracheobronchial glands into the bronchi were assumed. Multiple lesions, developing at intervals, indicating persistent bacillæmia, cause us almost to despair.

Pottenger (1944) wrote that his conception of clinical tuberculosis was that of a disease accompanied by repeated episodes of metastasis and body reaction, each of which, according to its relative severity, strengthened or weakened the host's resistance: "New infection is prevented or accomplished, and the patient cures or kills himself according to the sum total of the effects of the multiple invasions . . . an endogenous source of reinoculation requires above all other tuberculous lesions prolonged treatment, rehabilitation, and aftercare."

TREATMENT

In the recumbent treatment of bone and joint lesions it has many times been observed that associated pulmonary disease tends to improve, sometimes in a remarkable way, *so much so that one does not hesitate to adopt* a plaster bed in the deliberate treatment of lung lesions where other less tedious means are not applicable. Were the lesions skeletal, the surgeons might plan much longer periods in plaster beds than we have so far attempted. Though Peck and Willis (1945) enlarged on the dangers of rest in bed, among which they placed lack of adequate pulmonary drainage, they perhaps underestimated the motility of ciliated epithelium and the fact that arrangements for frequent tilting in any plane can be made.

It is remarkable how readily patients face the prospect of a long recumbency in a plaster bed when spine or hip is affected by tuberculosis. One hesitates to confess bluntly to a patient who has submitted to many things that the usual gamut of treatment for his pulmonary disease has been unsuccessful, and to offer the alternative of a plaster bed for the bronchomediastinal gland affection; but patients receive this verdict and sentence with the same fortitude and acquiescence as their orthopædic counterparts. They will as steadfastly and cheerfully endure the long succession of uneventful days untroubled by the weekly weighings or thoughts of liberty which tend to obsess patients once some exercise is permitted.

The average duration of treatment may be no less than for spinal caries; but, unless one is indifferent to the *production of tubercle bacilli and the very poor outlook* of such unresolved conditions, it should continue until complete encapsulation and apparent quiescence are achieved. Tuberculosis is an inflammatory process which, if it is to be arrested, demands rest until the viable bacilli therein are liquidated.

The first principle of treatment is adequate rest. Ambulant bilateral artificial pneumothorax as an initial measure in pulmonary disease may or may not provide rest but is as poor a thing to offer any patient for first choice as ambulant treatment of spinal caries. The constitutional improvement so often manifest with recumbency and splinting in the fresh air we accept today as a matter of course, but the aim of exposure should be tonic and reflex, to which end a cool breeze is more potent than heat.

Chronic inflammation of lungs leads to formation of fibrous tissue, with compensatory emphysema, and even normal lungs have but a brief period of maximal functional capacity, which varies somewhat between individuals owing to the inherited quality of their tissues. Inflammatory degenerative changes suggest that there is *more truth in the statement that* a man is as old as lungs than in the more often cited arteries or [illegible] The capacity to absorb oxygen is reduced, and in otherwise healthy person an increase of 10-15% above normal in the hæmoglobin content of the blood would be *anticipated as a compensatory* phenomenon. It follows that adequate transfusion of packed red cells to raise and maintain the hæmoglobin above 100% in patients with chronic tuberculosis whose hæmoglobin is deficient, and who rarely respond well to the exhibition of iron, may be expected to have a dramatically beneficial effect, reducing toxæmic symptoms, improving local disease, and increasing the tolerance of bilateral collapse measures in the chest. Psychological improvement is common, and the amount of optimism which can be injected with the red cells from three pints of blood must be seen to be appreciated.

A pulmonary cavity will not usually close and remain closed while the draining bronchus is the site of disease or is surrounded by diseased glands. Neither foreign-body occlusion nor complete bronchus stricture is surgically sound, and this mechanism of cavity closure, though it may work sometimes, is *less attractive* than a healthy bronchus giving free drainage and a free airway. It is a common experience, in suction drainage of a tuberculous cavity of the lung, that the secretions become serous, *tubercle bacilli* are *temporarily absent,* and partially occluded bronchi often become fully patent. It is doubtful if thoracoplasty should be performed for any considerable cavity before demonstrating that the draining bronchus is patent. Instead, suction drainage should be established *until the airway* is free, or else maintained during and after the major surgical procedure.

The occurrence of this chronic, progressive, and obstructive bronchomediastinal adenitis in pulmonary tuberculosis is sufficiently common to impress one with the need of its early diagnosis and subsequent modification of the plan of treatment. There is no more inaccessible disease process in the human body; but, in summary, treatment is regulated by the foregoing considerations, in which emphasis has been given to strict recumbency, open air, and a high hæmoglobin concentration, maintained, if necessary, by repeated blood-transfusion.

Local measures of splinting of parenchymatous disease may continue and are indeed required as urgently as when uncomplicated by obstructing lymph-nodes. *Some additional risk is associated with artificial* pneumothorax, and effusions are common. Particularly with excavation in the lower lobe, diaphragmatic paralysis and pneumoperitoneum may be nearly as effective and much less dangerous.

My general practice in bacillary positive pulmonary tuberculosis is *to* induce an artificial pneumothorax or, if necessary, bilateral collapse, divide intrapleural adhesions, and be prepared to get out at any time. If cavities balloon, persistent atelectasis develops, or effusions prove troublesome, I substitute interruption of the phrenic nerve and pneumoperitoneum.

After a trial of these measures, if the sputum or the gastric fluid still contains tubercle bacilli, bronchoscopy may be undertaken to inspect the air passages. Generally it is not a necessary adjunct of treatment before this time, and *even then* negative findings only exclude a fistula or a constriction of a bronchus from a limited field. Such lack of positive bronchoscopic evidence should not deter diagnosis of bronchomediastinal disease and the return of the patient to the most strict recumbency.

When major surgical collapse is carried out in *the* presence of bronchomediastinal disease, *the* persistence of bacilli in the sputum is to be expected. The criteria of quiescence following thoracoplasty tend to be somewhat lax compared with those measures with less finality about them, and the use of culture or of guineapig ioculation of centrifuged gastric contents to determine he bacillary state is less common than in pulmonary isease otherwise treated. The end-results of thoracolasty would be improved if the high incidence of central landular disease in cases requiring that operation were ccepted and treatment were prolonged until secretions rere free of tubercle bacilli by the most rigid tests.

SUMMARY

Regional tuberculosis is very often due to vascular lissemination from mediastinal adenitis.

Tuberculous mediastinal adenitis is likely to cause epeated bacillæmia.

Sometimes it causes endobronchitis, with collar-stud ibscess, and sometimes pleural effusion.

Bronchomediastinal tuberculosis is often found (1) in children; (2) in adults with minimal radiological evidence of pulmonary disease but with positive sputum; and (3) in patients with cavities in whom collapse therapy gives no benefit.

Prognosis of bronchomediastinal tuberculosis depends on (1) elimination of the superficial part of an abscess as a source of toxæmia; (2) control of the deep end of the collar-stud abscess by general measures, local splinting, or excision; (3) encapsulation or quiescence of the gland; and (4) constitutional factors.

Treatment is based mainly on strict recumbency, open air, and the maintenance, by blood-transfusions if necessary, of a high hæmoglobin concentration, combined with the usual local measures.

CEREBRAL AMŒBIASIS TREATED WITH EMETINE

REPORT OF A CASE

PATRICK COLLARD
M.B. Lond., M.R.C.P.
LATE RESIDENT MEDICAL OFFICER

DAVID KENDALL
D.M. Oxfd, M.R.C.P.
LATE PHYSICIAN

HURSTWOOD PARK NEUROSURGICAL UNIT

THERE seem to be no published examples of cerebral amœbiasis followed by recovery, so the case recorded here is of considerable interest.

A sergeant in the regular Army was admitted to the medical wards of the neurosurgical centre at Haywards Heath on August 4, 1943, from another hospital. Three weeks previously he had suddenly become ill, developing pain over the right lower ribs anteriorly and fever. From then onwards he continued to have fever, malaise, nausea, and chest pain which was aggravated by coughing and deep breathing.

He had served in the Middle East eight years, during which he had had numerous attacks of diarrhœa, but had never been diagnosed as having amœbic dysentery. He returned to this country a fortnight before he was taken ill.

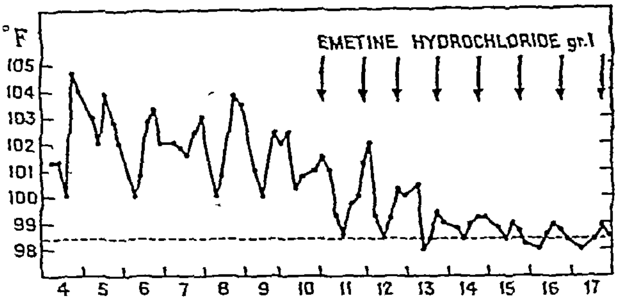
On admission he appeared cachectic, was sweating profusely, and had a very dirty mouth. Temperature 101·4°F, pulse-rate 84, respiration 20 per min. Abdomen not rigid or tender; liver and spleen not palpable.

Examination of the nervous system showed weakness of right external rectus muscle, moderate neck rigidity, and a bilateral positive Kernig's sign.

A few basal crepitations in chest. No abnormality discovered in cardiovascular system.

Investigations.—Lumbar puncture on August 5 gave clear colourless fluid under a pressure of 110 mm., no block, total protein 180 mg. per 100 c.cm., 10 lymphocytes per c.mm.

Blood agglutinations on August 5 negative to salmonella and brucella organisms. Radiogram of skull on August 6 normal. Blood-culture on August 10 sterile. Paul-Bunnell test negative.



Fall of temperature by lysis after emetine.

White-cell count 14,200 per c.mm. (polymorphs 83%, lymphocytes 15%, monocytes 2%).

Urine normal chemically and microscopically, culture sterile. No amœbæ or *Entamœba histolytica* cysts found in stools. Five stool specimens were examined by Dr. Joseph Bamforth and Dr. J. N. Cummings.

The patient continued to have a remittent fever up to 101°F in the evenings, and his general condition remained unchanged.

On August 10 lumbar puncture was repeated. The fluid was clear and colourless at a pressure of 90 mm. Total protein 60 mg. per 100 c.cm.; 17 lymphocytes per c.mm.

On August 11 the patient developed definite tenderness in the right upper quadrant of the abdomen. A friction rub was now audible over the 5th right intercostal space in the erect and supine positions. The rub disappeared on turning the patient on his left side and was therefore regarded as an indication of perihepatitis. The liver was tender and palpable an inch below the costal margin.

A course of emetine hydrochloride gr. 1 every night was begun, and within 48 hours improvement was evident. The temperature began to fall by lysis (see figure), the patient began to feel better, and the pain in the chest became less severe. After six days (August 16) the friction rub was no longer audible, and the right external weakness had recovered, but there was now some weakness on the right lower face.

By August 17 the fever had become intermittent, rising in the evening to 99°F, and the malaise had vanished, but there was still an aching pain in the right lower chest.

On August 24 a third lumbar puncture was done. The fluid was clear and colourless, under normal pressure, with total protein 70 mg. per 100 c.cm. and 1 lymphocyte per c.mm. The liver was still tender and just palpable.

On August 27 convalescence was interrupted by an acute right-sided lobar pneumonia, which responded satisfactorily to sulphathiazole, and by Sept. 15 the patient was afebrile, with no abnormal signs in the chest or nervous system, and the liver was no longer palpable.

On Oct. 22 the chest was examined by screening. This showed the right dome of the diaphragm to be raised and moving poorly on respiration. The patient was sent on leave, and on his return on Nov. 8 he was given a course of E.B.I. gr. 10, at the end of which he was feeling well and was free from abnormal signs in the central nervous system, abdomen, or chest.

Further radiography of his chest on Dec. 1 still showed the right dome of the diaphragm to be raised and deformed.

The patient was kept under observation as an outpatient, and when last seen on Feb. 26, 1944, he was symptom-free and no abnormal signs were elicited on physical examination. Sigmoidoscopy was performed once, but nothing abnormal was found.

COMMENTS

The diagnosis in this case was based on the history of diarrhœa in Africa, the appearance of a hepatic rub and tenderness, and the dramatic response to emetine. This combination was thought to be a sufficient basis for the diagnosis, in spite of the negative results of stool examinations.

Amœbic infection of the brain has been recognised for many years, having been described by Morehead in 1856. Amœbæ were first demonstrated in the abscess cavities by Kartulis (1904). Legrand (1912) described a case, and Armitage (1919) collected 48 cases from the literature. None of these workers, however, reported any recoveries. Neither craniotomy and evacuation of the abscess cavity nor treatment with emetine met with any success.

The patient reported on here was presumably treated much earlier in the development of his cerebral lesion than were those who died. It seems likely that he had only foci of amœbic encephalitis, which never proceeded to abscess formation. According to Armitage (1919) "the process originates from small areas of true amœbic meningitis, the infection reaches the depths of the nerve tissue." This concept may well be correlated with the clinical findings in our patient, who presumably was cured before any significant invasion of the brain tissue had taken place. The transitory cranial-nerve palsies must be regarded as an indication of a basal amœbic meningitis.

Reviews of Books

Forensic Medicine

Keith Simpson, M.D. Lond., lecturer in forensic medicine, Guy's Hospital, London. London: Edward Arnold. 1947. Pp. 335. 16*s*.

This short textbook, well printed on good paper, is intended primarily for the student, the general practitioner, and the barrister. Subject matter is well chosen, illustrative and vivid case-histories being briefly quoted in support of the text. The legal sections are concise and adequate. The 114 illustrations are mostly good and always instructive. This book is the work of an expert with a wealth of material at his disposal. The practising pathologist is bound to find something of interest in it, though he will doubtless hope to see at some later date a more exhaustive volume, complete with references, by the same author.

The Psychology of the Unwanted Child

Agatha Bowley, Ph.D., psychologist to the school psychological service, Leicester. Edinburgh: E. & S. Livingstone. 1947. Pp. 112. 6*s*.

This is a useful and timely book. Though well written, it demands only a modest degree of literacy in the reader, and can therefore be recommended to the kindly but ignorant who are venturing on the hard task of caring for the unwanted and unloved child. Miss Bowley teaches psychology through vivid and convincing examples. She goes on to give advice whose only defect is a certain excess of dogmatism. The art of upbringing is to treat the child rather than the behaviour, and this is perhaps obscured a little in her sensible lists of Do's and Don'ts. This does not detract from the value of the book as an introduction, especially for trainees who have experienced teachers to point out the subtleties that are here sacrificed to lucidity.

Handbook of Preventive Medicine

Air Ministry. Air Publication 1269B. London: H.M. Stationery Office. 1946. Pp. 312. 7*s*. 6*d*.

Responsibility for the health of a military unit rests ultimately with the commanding officer, but in the nature of things this duty will devolve for the most part on the medical officer. Ignorance of the practical aspects of preventive medicine is an almost invariable characteristic of the doctor newly joined from private or hospital practice, and if he is wise he will make full use of a textbook such as this. Among civil publications there is no equivalent to the Service manuals of hygiene. This short book, in a loose-leaf binding, includes chapters not only on water-supplies, conservancy, and communicable diseases but a detailed consideration of environmental hygiene. Indeed so much useful detail has been compressed into this chapter that one regrets that the chapter on water-supplies in the field does not supply all the information the harassed medical officer is asked to supply at a moment's notice; one might add that the advised quarterly testing of an established water-supply is hardly sufficient for safety. There is little unnecessary matter, though the make-up of the vitamin-B complex might have been abbreviated to less than half of the space devoted to diet; the illustrations are good and the index sets a standard higher than is usual in Service manuals. At the risk of adding a little more length it would be helpful if this book contained references to the Air Council Instructions and other regulations concerned; there are few more dreadful tasks than a search through volumes of official instructions—supplemented, amended, and cancelled—to find authority for some routine procedure.

Uterotubal Insufflation

I. C. Rubin, M.D., F.A.C.S., clinical professor of gynecology, College of Physicians and Surgeons, Columbia University, New York. London: H. Kimpton. 1947. Pp. 453. 50*s*.

This book, though not for the general reader, will be welcome to the specialist. As the originator of uterotubal insufflation, Professor Rubin writes with authority, and his book is one of the most comprehensive and thorough discussions of the method so far published. Illustrative cases, kymographic records, and X-ray plates have been skilfully chosen, and there are innumerable drawings (some of them rather fanciful) and tables. He deals in detail with the anatomy, physiology, and pathology of the fallopian tubes, and their relation to ovarian function. The technique of insufflation is minutely described, and its diagnostic and therapeutic value and its dangers are compared with those of uterosalpingography. He sent out questionaries to some 3000 workers using insufflation in all parts of the globe, and from replies received has constructed tables giving information about some 70,000 insufflations. A bibliography of nearly 1000 references also testifies to the care and thoroughness given to this work.

Asclepius

A Collection and Interpretation of the Testimonies. Emma J. Edelstein; Ludwig Edelstein. Baltimore: Johns Hopkins Press. London: Oxford University Press. In 2 vols. 1946. Pp. 470 and 477. 50*s*.

This fine work is for the student and connoisseur of ancient history rather than the ordinary reader. But whether one is dealing with the legendary Asclepius or the mortal physician of that name, later to be deified as a man-god, the story is one of absorbing interest. The first volume may be said to be explanatory, while the second is devoted to analysis and interpretation of the data. It seems clear that Asclepius practised his art, with an ever-increasing reputation, about the Homeric era. Of his actual birthplace, life, and death little or nothing is known; but his fame as a healer of wounds and disease spread all over Greece, and preventive medicine was a factor especially extolled and practised in the Asclepian cults. In spite of the advent of Christianity the worship of Asclepius at Epidaurus and elsewhere outlived that of all the other Greek gods. He was indeed regarded as the Greek Saviour; *for was he not* the God of Medicine who performed miracles, cured the sick, and showed charity to all? Much of his devotion to humanity finds a parallel in the life and teaching of Christ.

Essentials of Syphilology (2nd ed. Oxford: Blackwell. 1946. Pp. 465. 25*s*.).—The first edition of Dr. Rudolph H. Kampmeier's informative book appeared in 1944. Unfortunately the new edition bears no evidence of recent revision, references still being confined to papers published before that date, and the only note on penicillin is the hasty paragraph crowded in at the end of the first edition. The value and drawbacks of penicillin treatment of syphilis can now be more accurately assessed, and it should have taken its place beside classical methods in the long section on treatment. This remains a solid and instructive textbook, though not now fully contemporary.

Corrigendum.—The English publishers of *Early Ambulation* (reviewed on June 7) and of *Renal Hypertension* (reviewed on June 21) are Blackwell Scientific Publications, of Oxford, and not Messrs. Baillière.

B.D.H. ŒSTROGENS

B.D.H. Œstrogens give relief in all conditions attributable to deficient secretion of the œstrogenic hormone of the ovary. The natural œstrogen, Oestroform, or the synthetic œstrogens, Stilbœstrol B.D.H. and Dienœstrol B.D.H., are indicated in the female for menopausal disturbances, delayed puberty, amenorrhœa, oligomenorrhœa, dysmenorrhœa and sterility associated with uterine hypoplasia, pruritus and kraurosis vulvæ and vulvo-vaginitis.

Dienœstrol B.D.H. may be given to patients who have reacted adversely to other synthetic œstrogens. Stilbœstrol B.D.H. or Dienœstrol B.D.H. may be given to the male in prostatic carcinoma in those cases in which the malignancy of the lesion has been established.

Control of Epidemics in Public Schools

Everyone agrees that boys or girls in residential schools found to be suffering from an infectious disease should be isolated—preferably in the school sanatorium—at the earliest possible moment; but when we come to the length of their detention, which turns on the duration of infectivity, there is diversity of opinion and practice. Nor is there unanimity on the advisability and length of quarantine for those exposed to infection. Quarantine, a term with a long and chequered history, has been defined[1] as "the limitation of freedom of movement of such susceptible persons . . . as have been exposed to communicable disease equal to the longest incubation period of the disease to which they have been exposed." Its value as a measure of control can be assessed on its results in practice, but its duration for any particular infectious disease is difficult to decide until we possess more accurate knowledge of the length of incubation periods in terms of infectivity.

In his presidential address to the Medical Officers of Schools Association (p. 1 of this issue) Dr. R. E. Smith recalls that at Rugby School quarantine gave place many years ago to observation during the incubation periods of those deemed to have been exposed to infectious diseases. As the result of his own experience and that of his predecessor, A. I. Smiley, he is satisfied that quarantine is an extremely wasteful procedure—a conclusion which was reached by Scott[2] from his analysis of its results in the quarter of a million members of the Post Office staff. At Rugby from 1933 to 1947, of 203 boys exposed to one or other of the common fevers about half had had no previous attack, yet only 3 boys suffered clinical attacks, and in the sixteen years 1931–47, during which 75 outbreaks of infectious diseases occurred at the school, "not one of the originators had the slightest idea that he had been exposed to infection." A "susceptible" to an infectious disease is prima facie one who has not had a previous overt attack or who cannot be shown to possess immunity by specific tests where these exist; but, as Dr. Smith shows, besides those presumably immunised by previous attacks there are many boys who have had either doubtful attacks in earlier years or no recognised attack at all, and who yet pass unscathed through several epidemics. He thinks they are "probably" immune. It has long been known from the results of Schick and Dick tests that large numbers of children become immune to diphtheria and to scarlet fever—that complication of hæmolytic streptococcal infection, as Scholes,[3] of Melbourne, regards it—without suffering overt clinical attacks. The cultivation of viruses on chick embryos now includes the causal agents of mumps and measles. Complement-fixation tests carried out with mumps virus and blood-serum have enabled the members of the American Army commission on measles and mumps[4] to determine that whereas only 60% of the population of the U.S.A. gives a history of clinical mumps, 33% of young adults possess a high degree of immunity to the disease. Stokes,[5] discussing the use of gamma-globulin derived from large pools of adult blood plasma, concludes that "the presence of antibodies against infectious disease in human plasma appears to depend upon exposure to antigenic stimuli resulting from both subclinical or inapparent infections and from clinical infections." Thus Dr. Smith's "probably" becomes virtual certainty. But his conclusions are based on boys of public-school age exceptionally fortunate in their school environment, and one should bear in mind the cautionary note of the school epidemics committee of the Medical Research Council[6]:

> "Great differences," they say, "in house organisation are to be found especially in the boys' schools, while in standards of accommodation wide variations occur not only between different schools, but between different houses in the same school, and between different dormitories in the same house. All these variations complicate epidemiological questions to an extent which renders comparative deductions very difficult."

Abolition of quarantine might succeed in public schools where the basal immunity to the common fevers is relatively high, and the attack-rates consequently low, but be unsuited to preparatory schools receiving children of lower age-groups containing a large proportion of susceptibles. Nevertheless, epidemiologists on both sides of the Atlantic do not recommend quarantine as a measure of control of the common fevers except in one or two instances and then in modified form.[1] As to isolation, there is no doubt that the periods still imposed in some school sanatoria, and in some fever hospitals for that matter, are unduly long and result in unnecessary pressure on the accommodation, tedium for the patient, and dislocation of parental plans for the holidays. For this the various and varying "codes" are in part to blame; and it is to be hoped that a uniform procedure, such as that followed in the U.S.A. since the code of the American Public Health Association was officially adopted, will be possible here.

In such bacterial diseases as diphtheria (rarely encountered in public schools), scarlet fever, and whooping-cough, the bacteriologist can tell us, with varying degrees of certainty, whether the patient is yet free from infection, but in the virus diseases length of infectivity is still based on empiricism and experience. Yet, as Dr. Smith points out, the length of infectivity is influenced by such factors as climate and the health of the tissues attacked. Thus it is reasonable to conclude that healthy public-school boys are infectious for a shorter time than the average, and that earlier release from isolation is thereby justified. But if this is so, it will be impossible to determine by planned experiments a constant period of infectivity in individual virus diseases, which is what Dr. Smith desires. A duration of infectivity worked out in public-school boys would not necessarily be applicable to the child in the tenement. Dr.

SMITH believes, like the late J. D. ROLLESTON and most other epidemiologists, that in mumps swelling and infectivity disappear simultaneously. In measles, too, infectivity has certainly ceased by the time the rash has faded, and Dr. SMITH's criterion for freedom from infection—4 or 5 days' convalescence after the temperature is normal—is ample. As to scarlet fever, next to the progressive decline in the severity of the disease, nothing is more remarkable than the shortening of the period of isolation in fever hospitals, a change in practice initiated, or at least accelerated, by A. C. PARSONS's report [7] 20 years ago. The 6 weeks' detention for the uncomplicated case, which was then usual, became 4 and of recent years 3–4 and in a few hospitals not much over 2 weeks. Hence the month's detention that Dr. SMITH advocates is even a little generous. Incidentally, it has been shown [8] that the dangerous carrier of the hæmolytic streptococcus is not the pharyngeal but the nasal carrier; hence the importance, if terminal swabbing is resorted to, of including the nose. The experience with whooping-cough at Rugby School is unusual inasmuch as catarrhal symptoms were absent and vomiting and whooping were infrequent—another difference between patients of public-school age and younger children. The schoolboys probably possessed some degree of immunity which modified their attacks. Dr. SMITH believes that by the time the whoop arrives a schoolboy will be free from infection, but this is certainly not always true of younger children, whose postnasal swabs are sometimes positive for *H. pertussis* in the second or later week of the paroxysmal stage.

Dr. SMITH has given a valuable lead; his experiences should be extended and diversified by medical officers of other schools and the combined findings presented, perhaps, in a further report by the school epidemics committee of the M.R.C. It is only by such means that epidemiological problems can be viewed in their entirety and in correct perspective.

The New Zealand Scene

IT is now nine years since the New Zealand Social Security Act was passed, and for the last five of these years its principal medical provisions have been in operation. The developing pattern of the Dominion's health services is growing clearer, and a time has come when one should be able to assess gains, recognise mistakes and shortcomings, count the cost, and possibly suggest changes and extensions. All this is attempted in a short but instructive book [9] by Mr. DOUGLAS ROBB, of Auckland, and it is remarkable how many of the topics he deems of current and urgent importance in New Zealand are ones that also demand attention here in Britain. The great shortage of nurses, the unexpectedly high wastage of nursing students during their training, the scarcity and maldistribution of full-time consultants, and the lack of postgraduate instruction for general practitioners—these are our problems too. In addition ROBB touches on the need for more and larger medical schools in New Zealand, and makes interesting comments on reform of the medical curriculum, and on the relative importance of the subjects taught to students. But for readers here the most important sections of his book are those that survey the progress made so far in the State provision of general-practitioner, hospital, and consultant services in New Zealand.

Of the general practitioners a few, in sparsely populated areas, are paid by salary; a few are paid by capitation fee; but the large majority choose to be paid on an item-of-service basis, by direct claim or by one of the "refund" systems.[10 11] For each item of service given, the State gives the doctor 7*s.* 6*d.*, beyond which additional payment is often arranged with the patient. As was to be expected when fee-for-service claims were chargeable to a "bottomless" fund, a premium has been placed on quantity rather than quality of work, and ROBB is able to write:

> "The emphasis is placed . . . on the number of acts done rather than on quality. Indeed we find the doctor personally doing a number of trifling things in his practice that ought to be done by a nurse or secretary, but are not so done because it is worth 7*s.* 6*d.* a time to the doctor if he does them.
>
> "The distribution of doctors under present arrangements is interesting. The poor man's cough is now as profitable as the rich man's, and certain areas both urban and rural formerly poorly served have now medical men on the spot. So far so good, but a further effect is to concentrate medical men in the cities as against country districts where the travelling is greater, and where social amenities are fewer. Moreover, as between general practice on the one hand, and specialist, scientific, and teaching work on the other, there is a disproportionate attraction to the former.... The quality of service rendered under general practice suffers under the 'fee-per-service' structure, with its emphasis on quantity rather than quality. The tendency inevitably is towards quick superficial work, and the avoidance of difficult subjects, times, and places. The patient in genuine need of help at night or during a holiday is too often at a serious disadvantage."
>
> "Perhaps the worst feature of the present arrangements for general practice lies in their assumption that the style and scope of general practice as we knew it before 1940 was good and left nothing to be desired. Only make it universally available and all will be well! The truth is that many medical leaders had become more than doubtful of this proposition, and were trying to wean both people and doctors away from their addiction to the old style and methods with their inevitable bottle of medicine. Far from helping this endeavour, the Social Security Act has confirmed the old methods, and entrenched their already vested interests with richer rewards than ever."

The truth of these remarks is borne out by a study of the pharmaceutical costs. In the year 1942–43 these totalled £563,247. In the following year they exceeded £760,000, and we then commented[11]: "This sum represents a drug expenditure of 9*s.* per head of population, and as it excludes all medicines supplied to inpatients in hospitals, and takes no cognisance of any expenditure on patent or other remedies privately purchased, it seems unexpectedly large. One must conclude that the new service has not deterred, but rather encouraged, 'the bottle of medicine habit'." Now, two years later, the annual expenditure has risen to £1,133,366, or 13*s.* 6*d.* per head of population. The sum paid for drugs is nearly as much (78%) as the sum paid out for general edical care in the same year. But the costs to the tate of general medical care have been rising too, and OBB says:

> "Under these schemes, the doctors have rapidly become extraordinarily prosperous. It is comparatively easy to work up a good income almost anywhere, except perhaps in rural districts where a lot of travelling is still necessary. Actual figures of doctors' incomes are not published, but some which are almost fantastic are commonly mentioned in Parliament."

nd yet it is difficult to understand how this comes bout, unless there are large undisclosed sources of ncome from private practice, for the amount being aid out by the State per year still only amounts to 6s. 10½d. N.Z. (or about 12s. 9d. English money) er head of population, a capitation fee that would ardly be regarded here as adequate, particularly s the ratio of practitioners to population in New Zealand makes it unlikely that the practitioner can on average care for more than about two thousand patients. True, there are also payments for maternity work and in some practices for mileage; but even if these extras are included in the general-practice budget the annual income from State sources does not exceed the equivalent of 15s. English per capita Moreover, among these payments are some that are being made to full-time or part-time specialists for consultant services, for as ROBB points out:

> "Under Social Security any patient may claim a refund of 7s. 6d. per attendance by a specialist, whether in hospital or consulting-room, on presenting the receipted account. This provision was made partly as a relief to those incurring specialists' bills, and is a considerable relief, particularly to patients whose hospital stay is a long one."

It must not be forgotten, too, that quite large numbers of the doctors working in general practice in New Zealand have taken higher qualifications, and could well claim to be regarded as part-time specialists. ROBB is aware of this but a little undecided about the desirability of encouraging the continuance or extension of the tendency. He remarks on the high proportion of New Zealand graduates who have travelled to Britain or the United States for special postgraduate experience and study, and says of them:

> "A large number returned to New Zealand—more than could be occupied as genuine medical or surgical consultants. The majority combined general practice with medicine or surgery in a main centre, country town, or even small town, perhaps in later years dropping the general work, and practising as consultants. A few have succeeded in consulting practice from the outset, but only in the main centres.
>
> "This system over the years has brought a large amount of good practical experience to the country. . . . It has produced the characteristic all-round man whose type is admired by many in New Zealand—the man who will do a large general practice, with obstetrics and anæsthetics, and also hold a visiting medical or surgical post at a large hospital. This type has certainly produced great labours, and for general competence and commonsense he would be hard to beat. He showed at his best in a country town with a small hospital. In a large town he was often very successful but tended in time to lose interest in his general work, and at the same time to be overshadowed in his special work by his colleagues who were in straight-out consulting practice. Some have in time become good consultants, but others, through years in general labours, and the unavoidable loss of the student and scientific attitude, have never attained a good level.
>
> "The few who have attempted consulting wo from the beginning have as a rule achieved more in medical sense, but have been hampered by the gener status of the hospitals, the arrangement of appoin ments in the hospitals, and the general scantiness laboratory, scientific, and library assistance. Moreove consultation has never been fully used in New Zealan largely owing to the circumstances referred to under t 'all-round man' where consultation often seeme superfluous to both doctor and patient."

It becomes obvious that ROBB is himself hoping f conditions which will favour a functional separatio of general practice and specialism, leaving the pr ventive, educational, and psychological approac particularly to the general practitioner, while th specialist concentrates on a higher technical skill an perhaps on a more critical mental attitude to ne developments in medicine. ROBB maintains tha "no man can serve his patient adequately as bot general practitioner and specialist—one branch o other, or both, will be done poorly." Rather h believes that "general practice should be planned i health centres, and that specialist practice shoul be based in the general and special hospitals, wit outpatient departments or polyclinics for consultation and investigation. The one arm should utilise th other freely for help whenever possible, but it onl perpetuates present confusion to have dissimila functions performed by the same man in the sam place." He holds that New Zealand is too small country to afford both public and private hospita and consultant services, and he therefore favours salaried specialist service based upon government provided hospitals. He believes that New Zealan should have tackled the problem of hospital provisio much more radically than it has. He commends th courage with which the new Act in Britain sets ou to weld all the hospitals in the country into one system New Zealand has been content to allow its hospital to continue under their former ownership and management, and has arranged for the payment of grants in-aid in respect of all patients using the hospitals These were at first 6s. per day, and are now 9s. pe day; they are payable in all hospitals, public an private alike, the difference being that whereas i public hospitals any cost beyond this grant is born by rates or taxation, in private hospitals the patien has to make up the deficit. And ROBB explains tha private-hospital costs and fees have risen so steepl of recent years that the benefit to the patient of thi grant-in-aid is hardly noticeable. The smaller privat hospitals—of the type we should call nursing-homes— find it hard to keep going.

> "The Government through the Health Department in an apparently laudable endeavour to raise standard in these smaller hospitals, have imposed condition that are impossible of fulfilment, and if possible woul be prohibitive in cost. The result is almost a wholesale closing down of smaller private hospitals, particularly maternity homes. For example, during th twenty-two months ending in September, 1946, th number of private maternity hospitals dropped from 172, representing 1059 beds, to 113, representing 700 beds."
>
> "No one would say these private hospitals are ideal but many do good work of an individual type which constitutes a real community service. At least they carry part of the burden of hospital services of the country, and until the public system is rationalized and made adequate to its task, we can ill afford to lose them —perhaps not even then."

The cost of the social services to New Zealand is very high. Even at this time of full employment, and among a population with a comparatively small proportion of elderly people, the cost represents a charge of over 10% of the gross income of the inhabitants. So far they seem uneasily conscious that they are getting less for this great expenditure than they have the right to expect:

> "The people as a whole want something better than they have got. Political power at the moment is fairly evenly divided in the country, and there is reason to believe that both parties have accepted the broad idea of the social organization of health services, and also are aware that what we have got under that guise at the present time is, for a variety of reasons, inefficient, wasteful, and altogether unworthy of the people and the country."
>
> "The Social Security scheme at present operating in New Zealand attempts to provide the benefits of modern medicine for everybody. But it offers a service far inferior to that which modern medicine *could* give us. At the huge price paid, it is dearly bought."

ROBB concludes that "it should be our aim—and more specifically the aim of the government and of the medical profession—to plan a service based on *function*: that is to say, on the real needs of the people, and the capacity of the medical profession, with all the resources of modern knowledge and organization, to meet those needs."

Mechanical Aids in Cardiology

SINCE the fashion was set up by WENCKEBACH and MACKENZIE cardiologists have been pioneers in applied physics. One might even trace this line of development from STEPHEN HALE and his measurements of blood-pressure in the horse. The cardiologists of today are keeping pace with the rapid advances in physics and ingeniously harnessing the latest discoveries to the service of the patient with cardiovascular disease.

The development of modern electrical amplifying systems has given a new impetus to electrical stethoscopes. OLSON[1] has introduced an acoustic stethoscope which transmits the heart sounds very much more truly than the orthodox stethoscope which accentuates certain frequencies at the expense of others, so that the listener hears a series of sounds which are quite different from those actually produced in the heart. From the clinical point of view this may not be important, since the doctor soon establishes his own normal and learns to detect and interpret variations from it; but the research-worker may get some useful information from these new stethoscopes. It is in phonocardiography that the greatest advances have taken place. There are two methods of registering the heart sounds graphically: the direct, in which an optical capsule system is used,[2] and the indirect, in which a series of electrical devices amplify and record the sounds. A further refinement is MANNHEIMER's[3] calibrated phonocardiograph, in which the heart sounds are split into six frequency bands. Another development, which should be invaluable for teaching, is the accurate amplification of the heart sounds so they can be heard by groups of students, either with headphones or a loudspeaker. For this purpose they can be recorded on a disk,[4] on cinema film, on wire tape, or on plastic or paper tape coated with a finely divided metallic powder.

In electrocardiography the string galvanometer is being replaced by electronic-valve amplifiers, robust mirror galvanometers being used for recording. Valve amplifiers, with mechanical recorders which trace the electrocardiogram on a miniature scale, have been devised, and cathode-ray tubes, especially those fitted with a long-persistence screen, are increasingly popular. Mirror galvanometers with ultraviolet light as the source of radiation and lag-belt viewing screens are also being used, and ink-writer recorders have been adapted for this work. As a result of these refinements it is now possible to register the electrocardiogram of the embryonic chick[5] and the human fœtus.[6] LIKOFF and his colleagues[7] have made an electrocardiograph capable of recording continuously for up to twenty-four hours. Œsophageal and even intracardiac leads are sometimes used. Another development is the recording of the vectorcardiogram on the screen of a cathode-ray tube,[8] this being a graphic representation of the magnitude and direction of the electromotive force produced by the heart at a given instant. Hitherto the vectorcardiogram has had to be deduced from leads 1 and 3 of the electrocardiogram, a laborious process.

Multiple recording apparatus is sometimes useful in clinical work as well as in research and teaching. In the phonoelectrocardioscope[9] a double-beam cathode-ray oscilloscope makes it possible to follow, on a single long-afterglow screen, the phonocardiogram and electrocardiogram, or the phonocardiogram and sphygmogram, while the heart sounds are heard simultaneously through an electrical amplifying stethoscope or loudspeaker. Of the many methods of plethysmography, two may be mentioned. In the photo-electric method[10] light is directed through a finger or toe, and the emergent beam strikes a photoelectric cell which changes variations in the intensity of light, due to changes in the blood-flow to the part, into corresponding variations in an electric circuit. The electrical variations are amplified by a valve amplifier and recorded with an oscillograph. The electrical impedance plethysmograph is based on the principle that rhythmical changes in electrical impedance occur with each heart-beat, when high-frequency currents are passed through the body.[11] This method is so accurate that it makes it easy to register pulse curves from animals as small as the frog in states of shock, or from a small body segment such as a finger. In the radiography of the heart the R wave of the electrocardiogram can be made to operate the X-ray exposure so that it occurs at any desired stage of the cardiac cycle. Cineradiography[12] has also been combined with electrocardiography, and even contrast

diography of the chambers of the heart is now a actical proposition. Perhaps most startling of all the orthodox clinician is the optical recording of tracardiac pressure pulses by means of intracardiac theterisation.[13]

Annotations

THE MEDICAL PROTECTION SOCIETY

THE London and Counties Medical Protection Society ves its name to the time, soon after its foundation in 391, when provincial committees were set up to suplement the central council. With a membership of ver 22,000, in all parts of the world except the United tates, the society has long needed a more apt title; nd at the general meeting on July 16 members will be sked to approve abbreviation to The Medical Protection ociety.

With accumulated funds of over £112,000 the society in a strong position. During the past year, reviewed in he annual report, 1894 new members were elected, ompared with 1087 in 1945. Of the 1410 applications r advice and assistance, many were concerned with he implications of the National Health Service Act. everal topical subjects are covered by the society's olicitors, Messrs. Le Brasseur & Oakley, in their section f the report. It is not always understood, Mr. Le rasseur says, that where a practitioner has retired or ied in the period between the passing of the Act and he appointed day, and the goodwill of his practice has ot been sold, that practitioner or his representatives an apply for compensation payable under the Act for he loss of the right to sell the practice. Discussing roceedings for alleged wrongful certification under the Lunacy Act, the solicitor comments: "It is surprising that even in the legal profession it is not fully appreciated that no such proceedings will lie except with the leave of the High Court." He also recalls that coroners have no power to impose an obligation to notify them of all deaths occurring within forty-eight hours of admission to hospital. Most cases undertaken by the society involve allegations of negligence. Even when unjustly charged, some doctors are disposed to avoid further worry by settlement out of court; but no settlement, says the report, is ever secret.

Almost any member of our profession could find profit as well as interest in the records of misfortune and error given in this report.[14] Thanks to the society, they mostly had happy endings—at least so far as its members were concerned.

SOUR MILK AND TUBERCULOSIS

THE search for an efficient therapeutic agent in human pulmonary tuberculosis goes on intensively, but progress is difficult. For a drug to succeed in this field it has to overcome three obstacles over and above those present in the chemotherapy of streptococcal infections. The first is the relative resistance of the bacterium to drugs, possibly owing to its fatty constitution. The second is the necrotic and non-vascular nature of the lesions, as compared with those in other infections and indeed with those in experimental tuberculosis in animals, making them inaccessible to the drug. Lastly, in this chronic disease many drugs which are quite safe for the treatment of streptococcal infections show disturbing evidences of latent toxicity. The sulphone compounds, such as 'Promin,' 'Diasone,' and 'Promizole,' will retard experimental tuberculosis and have been given clinical trials but they are too toxic for general use in man. The same seems to be true of helvolic acid. Streptomycin has given even more promising results in animals, and has produced some startling remissions in tuberculous meningitis and miliary tuberculosis, but so far it has not fulfilled the early hopes in pulmonary infections.

Now the humble domestic lactic streptococci which turn our milk sour in hot weather may be pressed into service. In 1933 H. R. Whitehead noted that some milk streptococci prevented the growth of the organisms used in cheese making. Following this up at the National Institute for Research in Dairying,[1] Mattick and Hirsch discovered a strain of group-N lactic streptococci that could kill, or render avirulent, a heavy inoculum of human tubercle bacilli in milk. In this issue they give details of the purification and properties of Nisin, the antibiotic concerned. It is highly active against gram-positive bacteria, much less so against the tubercle bacillus, and inactive against gram-negative organisms. In this it follows the common pattern for most antibiotics. It keeps its activity in the presence of blood—a prime necessity for a therapeutic agent—and it is of low toxicity against leucocytes and in the intact animal, though the injection of impure preparations causes some necrosis. Its chemotherapeutic activity in animals is very striking. A single dose of 50 mg. saved mice which were in a moribund state twelve hours after 1000 lethal doses of a streptococcus. Ten years ago this would have appeared miraculous, but we have grown used to substances which can kill streptococci at incredible dilutions. In a preliminary experiment with impure material, nisin was found to limit but not prevent tuberculous infection in animals.

Nisin is probably not the long-awaited answer to the tuberculosis problem, but it marks one more step forward in man's advance against this ever-present foe.

THE COST-OF-LIVING INDEX

WE have already noted[2] the projected changes in the cost-of-living index recently accepted in principle by the Minister of Labour and National Service. He now proposes to act on the proposals for an interim index based on the results of a sample survey of 10,000 working-class household budgets done in 1937–38. The interim nature of this index is emphasised in the explanatory note announcing this decision[3]: as every woman knows, the range of choice in her purchases is now severely limited compared with 1938; while, on the other hand, an index based on today's purchases would, we fervently hope, be out of date fairly soon. Despite these limitations, the interim index, including as it does the near-necessities of modern life such as cinema tickets, soap-flakes, and children's wellingtons, will be a much more realistic indicator of the present pattern of expenditure. The inclusion of so many new items raises the question of the relative importance to be assigned to them in the calculation of the interim index; where in 1914, 60% of the budget was being spent on food, in 1938 food accounted for only 35% of the family's expenditure. This does not mean that less food was bought in 1938; indeed, greater quantities of food were purchased, but the relative proportion of the family budget spent on food was much less. The new "weighting" for food in the interim index thus becomes 35 instead of 60. Similarly, 24% of the "weighting" is now accounted for by items not covered in the 1914 index.

Such considerations may seem a trifle academic at this stage; but cost-of-living indices could have an urgent personal importance to doctors in the new health service. If, for example, remuneration scales were tied to cost-of-living indices, a decrease in the cost of meeting the needs of a working-class household would be reflected in a reduction of professional salaries. In other words what might be gained on the present inflationary swing might well be lost on a future deflationary roundabout. That, some may say, is only just; but if justice is to be dealt out in this way, then we may plead that the cost-of-living index for a middle-class profession should be based on the purchases required to maintain at least some of the necessities, cultural as well as dietetic, of middle-class existence.

A STREPTOMYCIN BUREAU

THE following statement has been issued by the Medical Research Council in association with the Voluntary Hospitals Emergency Bed Service:

> Doctors in southern England, including the London area, wishing to propose cases of acute miliary tuberculosis or tuberculous meningitis for admission to a Medical Research Council trials centre for streptomycin treatment should, from July 4, make their request through the Emergency Bed Service, London (telephone: Monarch 8515—day and night service). The service will be kept fully informed of the number and type of cases which can be admitted to each centre, and where a bed is available will direct the inquiry to the appropriate medical officer. It should be emphasised that the number of cases which it will be possible to admit for treatment during the period of the present tests is still limited.
>
> Trials of streptomycin in tuberculous meningitis in children aged up to eight years are also being made, under the council's authority, at the Alder Hey Children's Hospital, Liverpool, and the Royal Hospital for Sick Children, Glasgow.

This is excellent news. It means that doctors in the south of England will no longer have to explore a variety of official and non-official sources of supply when they have a patient with tuberculous meningitis or miliary tuberculosis. Henceforward the telephonists of the Emergency Bed Service will quickly put the doctor in touch with a representative of the Medical Research Council, who control the distribution of all the streptomycin made in or officially imported into this country. An obvious and urgent need is for a similar arrangement to be devised for the rest of the British Isles.

BETHLEM

THE Priory of St. Mary of Bethlehem, founded and endowed in 1247 by Simon Fitz Mary, has made good use of the past 700 years, and can be counted on to keep up the tradition, as Sir Arthur Rucker implied when he wished Bethlem Royal Hospital godspeed in the 700 years of service to the community now to come. He was replying to the toast of The Guests, proposed by Sir George Wilkinson, at the luncheon given in honour of the hospital's birthday at Monks Orchard, Beckenham, on June 28. He pointed to the immense opportunities the new era of administration is bringing to hospitals and especially to mental hospitals. There must be, he said, much closer association between the treatment of mental and physical illness; and he recalled the two great obstacles now hindering our advance in this and other directions within the health services—lack of buildings, lack of nurses. In proposing the toast of the hospital, Mr. Ralph Assheton, M.P., mentioned its links with the real Bethlehem, where the Basilica of the Nativity was endowed in the year A.D. 330 by Constantine—the only Roman emperor both born and proclaimed in Britain. The ancient bond between the church and the hospital served as preface for his plea that psychiatrists and ministers of religion should endeavour to work together more closely for the care of patients. In his reply, Sir Bracewell Smith, lord mayor of London, spoke of the proposed amalgamation between Bethlem Royal and the Maudsley Hospital. This proposal was approved by the London County Council at its meeting last Tuesday.

Bethlem, which moved from its old buildings in Southwark 17 years ago, is a modern well-equipped hospital, built on the villa plan; and takes 250 patients. The villas include an admission block, treatment block and a convalescent block; and there are besides an administration block, a unit for treatment and research containing laboratories and an up-to-date theatre, and a separate occupational therapy unit where patients can learn weaving, pottery, needlework, painting, basket-work, and other handicrafts. The kitchens and stores are housed in a separate building, with the engine-house alongside. The chapel stands close to the main gate, opposite a well-built nurses' home. All these buildings are set in ample wooded grounds which give room for orchards, lawns, a cricket field, tennis courts, and gardens. The home farm, placed at one corner of the grounds, supplies many of the hospital's needs. Patients' rooms are simply but pleasantly furnished, and painted in light colours; and the common-rooms—light, airy, and charmingly decorated—are the proper sort of surroundings for mentally sick people. If all our mental hospitals would accept this principle, the change might well be reflected in a higher recovery-rate.

During the afternoon of the birthday celebrations, H.M. Queen Mary, president of the hospital, paid it a visit. With an unerring flair for fundamentals, she inspected the kitchens. At Bethlem the part played by good food in the recovery of patients is appreciated; but there are other hospitals in the country where it seems they will never learn—not in 700 years.

PROPHYLAXIS OF WAR

> ". . . pacifists have found the atomic bomb a positive godsend. Their line of argument runs as follows: However fallible the methods adopted to secure world peace, they simply *must* be successful: . . . either we secure world peace or we face extinction in a last cataclysm: war has finally outlawed itself by reason of its immeasurable destructiveness."

Dr. Edward Glover, in his further essays on group psychology and war,[1] has the accumulated impatience of fourteen years to explode on us. The causes of war, he says again, are in the unconscious; and the causes of pacifism are identical with the causes of war-mongering. His argument is telling if long; briefly, our attitude to war is engendered and moulded by our infantile loves and hates. Frustrated love for the mother and jealous hate of the father are primary motives for rivalry between men; for since, as he points out, both primitive loves and primitive hates are by their nature destined to frustration, the strong instinctive drives which lie behind them must be used in other ways. As the child develops a superego (old terminology, conscience) he finds opportunity to use them. Hopeless love gives the superego power to approve whenever the ego obeys accepted canons; hopeless hate gives it power to avenge misdeameanours. The stronger the hate the greater the frustration, and the greater the sense of guilt by which they are punished. The child thus carries in him not only the power to punish himself but the ability to feel that punishment is deserved. In this way the superego, mirroring the strong and vengeful father of the child's guilty imaginings, uses up much of his thwarted aggression. But when the child comes to manhood and is called to serve in a war an extraordinary situation develops for his unconscious mind: he is called on to kill "the enemy," the rival, the other man, as he has so often killed the rival father of his fancy; and he is allowed to do this with full parental sanction—with the blessing, in fact, not only of the superego but of the "fatherland." For once he may turn all his aggression outward, and do his worst; he is given a free dispensation from guilt. But his unconscious guilt is not to be assuaged by a mere licence to practise crime: the need for punishment remains, and in war is fully satisfied—he may be killed himself. Herein lies, Dr. Glover thinks, the great unconscious appeal of war: it frees men to kill or be killed, or to die vicariously in the person of a comrade. The unconscious asks no more: it delights in this chance to escape from a lifetime of anxiety, frustration, and guilt.

---

[1] War, Sadism and Pacifism. London: Allen nwin. 1933 extended series 1947. Pp. 292. 9s. 6d.

Much of this is now common ground. Thus in an essay which has just been reprinted[2] Prof. J. C. Flugel writes more placidly of the same unconscious gratifications brought by war, together with others, such as pleasure in danger and adventure, in comradeship, and in the release from the daily round. Perhaps, indeed, Dr. Glover would find more open support for what he says if he did not say it so aggressively. Unfortunately, too, his anxiety to drive home the pathology has somewhat deflected him from prophylaxis. Here he has *little* to offer, for (as he himself says repeatedly) we really know next to nothing about the unconscious origins of war, and we spend very little time and money in finding out about them. In the first edition of this book he suggested a good plan of research; and it remains a good plan. Apart from this, "we ought," he says, "first of all to try bringing up children free from the avoidable anxieties, guilts and despairs that promote unconscious hostilities and so promote war-readiness." Exactly; but how is it done?

Meanwhile we are driven to think fast. However inept it may seem to Dr. Glover, the pacifist argument quoted above remains reasonable; and it is he who fails in realism. When chased by a tiger one does not pause to consider the unconscious motivation of big-game hunting. By all means let us try to discover the unconscious causes of war; if we live long enough the knowledge is sure to come in handy. In the meantime he must excuse us if we try to find a way out of our darkness by the dim glimmer of the conscious mind. It is just possible that we may blunder on some solution *acceptable* to our unconscious motives. If we can't be clever we must at least try to be quick.

NARCOTICS FOR THE FAMILY

ONE of the points raised by the case of Dr. Clements is how far a doctor may prescribe narcotic drugs for himself or for his wife or other near relation. If Dr. Clements had had no criminal intent, was there any reason why he should take precautions to conceal the fact that he was buying such drugs for his wife's use? The answer depends on whether the drugs come under the Pharmacy and Poisons Act or under the Dangerous Drugs Acts. The barbiturates are schedule-4 poisons, which means that they can be dispensed only on the prescription of a registered doctor, dentist, &c.; but, whatever the ethical objections, there is nothing in the law to prohibit any doctor on the Register, whether in practice or not, from prescribing one of these drugs for himself or his wife and family, and the chemist will normally dispense it without question, provided the dosage is reasonable. Narcotics of the morphine, cocaine, and heroin groups, on the other hand, come under the D.D.A. regulations, and though any doctor may prescribe these, he may have them in his possession only so far as is necessary for the practice of his profession. Any doctor on the Register may therefore prescribe morphine for himself or his wife if, for example, one of them has an attack of renal colic; and a doctor in practice may keep a supply of these drugs in stock. But a doctor who has retired from practice, or is engaged in some non-clinical branch of medicine, may not keep any dangerous drugs at all in stock, even though he is still a registered medical practitioner. If the doctor or his wife becomes an addict, the Home Office takes the view that to supply such a person with drugs is not in accordance with the doctor's authority, and if the doctor continues to order large quantities of drugs merely to maintain the addiction the Home Office will take action as soon as the matter comes to its notice.

TO ENCOURAGE MATERNITY

AMONG studies carried out for the Royal Commission on Population, a survey of childbearing in Britain, made by a joint committee of the Royal College of Obstetricians and Gynæcologists and the Population Investigation Committee, has just appeared.[1] The health visitors of 424 maternity and child-welfare authorities interviewed all mothers of babies born between March 3 and 9, 1946; and 13,687 of these mothers coöperated. Analysis of answers showed that childbearing is costly, the outlay ranging from £22 among wives of farm labourers to £47 for wives of professional and salaried workers. From two-thirds to three-quarters of the cost went on clothes and equipment, and only about a fifth on medical and institutional fees. For the lower-income groups the relative outlay in proportion to income is much higher than among the well-to-do, and they are also more likely to be confined at home, and to resume domestic duties and responsibilities earlier. In home confinements wives of professional and salaried men get relief of pain three times as often as the wives of manual workers. The committee conclude that there are still great inequalities in the care received by mothers of different degrees of prosperity. The high cost of childbearing can only be reduced by lowering the costs of baby clothing and equipment.

THE REGIONAL BOARDS

HAVING defined the 14 regions into which England and Wales will be divided for hospital purposes, the Minister of Health has now appointed the boards whose task it is to plan, coördinate, and provide hospital and specialist services in each area. The names which we print on another page will have general approval, and the new regulations, so far as they go, support the Ministry's claim that "the boards will enjoy the maximum measure of real freedom of action in exercising their responsibilities." Their first care will no doubt be to appoint officers, of whom the "administrative medical officers" are to be offered a salary of £2000–£2500 a year. They will then have to review their resources, consider how the hospitals should be grouped under management committees, and appoint the members of these committees. A formidable amount of work lies before them in the twelve months before the National Health Service comes into being.

AT the annual meeting last Tuesday, reported on another page, the Royal Society of Medicine's gold medal was conferred on Sir Alexander Fleming, F.R.S., and (in absentia) on Sir Howard Florey, F.R.S. The Hickman medal, awarded triennially for outstanding work in anæsthesia, was presented to Prof. R. R. Macintosh. The four new honorary fellows of the society are Prof. Naguib Mahfouz Pasha (Cairo), Prof. Einar Key (Stockholm), Sir Edward Mellanby, F.R.S., and Dr. C. M. Wenyon, F.R.S.

SIX leading pharmaceutical firms announce a reduction, from July 7, in the prices of coloured penicillin sodium salt and penicillin oil-wax suspensions. The prices of white penicillin are unchanged.

Special Articles

REGIONAL HOSPITAL BOARDS

MEMBERS AND PROCEDURE

THE Minister of Health has now set up hospital boards for the 14 regions of England and Wales which were defined last December and which are shown in the accompanying map. These boards are to act as the agents of the Minister for organising and developing the hospital and specialist services of each of their areas, and they are to "enjoy the maximum measure of real freedom in exercising their responsibilities." In their hands lies the appointment of the hospital management committees which will undertake the day-to-day administration of all hospitals in the region, other than the teaching hospitals which will have their own boards of governors appointed by the Minister.

In selecting the members the Minister has consulted a very wide range of organisations interested in hospital services, and besides experienced members of local authorities and of the governing bodies of voluntary hospitals they contain doctors, dentists, nurses, university teachers, industrialists, and trade-unionists. The total number in each board varies from 22 to 32. All the appointments are honorary and unpaid.

Roughly a third of the members will retire each year (they will be eligible for reappointment), and the following list shows the names printed in three groups: (*a*) those retiring in March, 1949; (*b*) those retiring in March, 1950; and (*c*) those retiring in March, 1951. (The chairmen will hold office till March, 1950.) The names of members of the medical profession are shown in bold type.

NEWCASTLE REGION

Chairman: Sir Walter Thompson, J.P. (chairman, Newcastle health committee).

(*a*) **T. H. Bates**, M.D.; Thomas Benfold, C.B.E., J.P.; E. F. Collingwood, C.B.E., J.P.; Alderman Alfred Cooper; **D. C. Dickson**, F.R.C.S.E.; John Foster; **William Fraser**, M.B.; J. A. Hutchison; Robert Muckle; T. A. Wright.

(*b*) Miss D. R. Gibson, S.R.N.; Prof. **R. B. Green**, F.R.C.S.; Prof. **W. E. Hume**, C.M.G., F.R.C.P.; **J. R. Murray**, M.D.; Lord Eustace Percy, P.C.; Viscountess Ridley; T. C. Squance, O.B.E.; William Waddell; Lord Westwood, O.B.E.

(*c*) Alderman A. J. Best, J.P.; Leslie Bird, M.B.E.; G. D. Cochrane, J.P.; Alderman Jack Cohen, J.P.; Alderman P. S. Hancock, O.B.E.; T. B. Harston; **R. E. Jowett**, M.D.; **G. P. Milne**, M.B.; Prof. **F. J. Nattrass**, F.R.C.P.; James Oliver.

LEEDS REGION

Chairman: J. E. Fattorini (chairman, Bradford Infirmary).

(*a*) Alderman H. J. Bambridge, O.B.E., J.P.; Alderman Lewis Chambers; Lawrence Crowther, O.B.E., J.P.; Miss Mary F. Dykes, S.R.N.; Prof. **William MacAdam**, F.R.C.P.; **D. C. Muir**, F.R.C.P.; Prof. **Matthew Stewart**, F.R.C.P.; Alderman Arthur Sugden, J.P.

(*b*) Alderman David Beevers, J.P.; **G. W. Black**, F.R.C.S.; Prof. **Andrew Claye**, F.R.C.O.G.; Harry Denham; B. Hazell, M.B.E.; W. L. Lawton, C.B.E., J.P.; **J. I. Russell**, M.D.

(*c*) S. Clayton Fryers; J. C. Hunter; **W. S. Macdonald**, M.C., M.B., J.P.; Mrs. I. Barbara Shaw; Alderman R. E. Smith; Prof. **R. E. Tunbridge**, O.B.E., F.R.C.P.; Arnold Walker; **Donald Watson**, F.R.C.S.

SHEFFIELD REGION

Chairman: Sir Basil Gibson, J.P. (late town clerk, Sheffield).

(*a*) Alderman C. F. Bowmer, J.P.; **J. W. Brown**, F.R.C.P.; Alderman Henry Deer, J.P.; Mrs. F. Julia Everard; A. W. Harrison; C. M. Hobson; Lord Quibell; Alderman Edward Sheorien, J.P.; Prof. **E. J. Wayne**, F.R.C.P.; Miss A. Wetherell, S.R.N.

(*b*) Miss **Margaret G. Bott**, F.R.C.O.G.; R. E. Dewberry; **K. K. Drury**, M.C., M.D.; **J. P. W. Jamie**, M.C., M.D.; A. R. Martin; Theophilus Pearson; Prof. **G. L. Roberts**, M.B., B.D.S.; E. W. Scorer, O.B.E.; Alderman Robert Shaw, J.P.; Alderman W. E. Yorke, J.P.

(*c*) Alderman W. Bayliss, J.P.; Malcolm Brown; Mrs. Gladys Buxton, J.P.; Prof. **E. F. Finch**, F.R.C.S.; Harvey Ford; **J. L. A. Grout**, M.C., F.F.R.; W. B. Jarvis; Lieut.-Colonel N. G. Pearson, D.S.O., M.C.; G. H. Round, J.P.; **A. B. Slack**, M.C., M.B.

EAST ANGLIAN REGION

Chairman: Earl of Cranbrook (county councillor, East Suffolk).

(*a*) Mrs. Hester A. Adrian, J.P.; C. R. Caselton; P. F. Dennard; **Robert Ellis**, M.D.; **T. S. Hele**, O.B.E., F.R.C.P.; **J. V. Morris**, M.B.; Miss J. G. Thompson, S.R.N.; Alderman Mrs. Mary Whitmore.

(*b*) Alderman John Brooksbank, J.P.; Alderman William Brown; **M. W. B. Bulman**, F.R.C.S.; Rev. Canon J. D. Day; **R. B. Fawkes**, D.S.O., M.C., M.R.C.P.; James Grantham; Alderman Sam Peel, J.P.; E. W. Plumpton, J.P.

(*c*) Mrs. Ena Binfield; **R. W. Butler**, F.R.C.S.; Oswald Chivers; J. B. Coster, J.P.; **W. B. Gourlay**, M.C., M.B.; R. B. Keefe; Sir Cecil Oakes, O.B.E.; R. H. Parker, M.C.; W. H. York.

NORTH-WEST METROPOLITAN REGION

Chairman: Fred Messer, M.P., J.P. (chairman, Middlesex county council).

(*a*) Colonel the Hon. J. J. Astor, J.P.; Mrs. Flora Baker, O.B.E., J.P.; **H. E. A. Boldero**, F.R.C.P.; Miss Vera Dart; Henry Fletcher; **Horace Joules**, F.R.C.P.; Alderman Mrs. Martin-Smith, M.B.E.; **A. C. Morson**, O.B.E., F.R.C.S.

(*b*) Miss Elizabeth Cockayne, S.R.N.; Prof. **S. J. Cowell**, F.R.C.P.; **A. S. Gough**, F.R.C.S.; Henry Lesser, O.B.E.; Prof. **J. M. Mackintosh**, F.R.C.P.; Sir Owen Morshead, K.C.V.O., D.S.O., M.C.; **J. R. Rees**, C.B.E., F.R.C.P.; Miss **Esther Rickards**, F.R.C.S.; Mrs. F. M. Suggate, J.P.; **H. W. C. Vines**, M.D.

(*c*) F. J. Ballard; **D. H. Brinton**, F.R.C.P.; G. B. Jeffery; Miss **Katharine Lloyd-Williams**, M.D.; Sir Alexander Maxwell; Alderman H. R. Neate; **L. W. Plewes**, F.R.C.S.E.; A. G. de Rothschild; Reginald Stamp; **Stephen Taylor**, M.D., M.P.

NORTH-EAST METROPOLITAN REGION

Chairman: J. W. Bowen, O.B.E., J.P. (late chairman, L.C.C. mental hospitals committee).

(*a*) Alderman C. E. S. Blackmore; Mrs. Hilary Blair-Fish, S.R.N.; Captain H. Brierley, O.B.E., M.C.; C. C. Carus-Wilson, M.C.; **Somerville Hastings**, F.R.C.S., M.P.; Alderman S. F. Johnson, J.P.; E. T. Neathercoat, O.B.E., J.P.; C. S. B. Wentworth-Stanley.

(*b*) Prof. **S. P. Bedson**, F.R.C.P., F.R.S.; **Louis Comyns**, L.R.C.P.E., M.P.; Lieut.-Commander Horace Denton; Miss **Helen Mackay**, F.R.C.P.; **Rolf Ström-Olsen**, M.D.; Major R. P. Woodhouse.

(*c*) H. W. Butler, M.P.; **George Graham**, F.R.C.P.; Mrs. A. L. Hollingsworth, J.P.; **Robert Poots**, M.B.; **R. W. Reid**, F.R.C.S.; Alderman C. H. Simmons, J.P.; W. V. Wakefield.

SOUTH-EAST METROPOLITAN REGION

Chairman: K. I. Julian (chairman, Royal Sussex Hospital, Brighton).

(*a*) Alderman R. H. Burslem, J.P.; F. W. Chambers, O.B.E., J.P.; Dame **Barrie Lambert**, D.B.E., M.B., J.P.; Alderman T. E. Morris, J.P.; Rev. Harcourt Samuel; **H. A. Treble**, B.M.; **J. R. H. Turton**, F.R.C.S.; S. J. Worsley, D.S.O., M.C.

(*b*) **E. R. Boland**, O.B.E., F.R.C.P.; Miss E. K. N. Cumming, S.R.N.; Lord Cunliffe; **F. E. Feilden**, F.R.C.S.E.; Alderman Miss Alice Hudson, M.B.E., J.P.; **A. T. Rogers**, M.B.; E. C. Sherwood.

(*c*) **C. W. Brook**, M.R.C.S.; The Hon. Ruth Buckley; **W. Kelsey Fry**, O.B.E., M.C., M.R.C.S., L.D.S.; Alderman S. C. C. Harris; The Hon. Mrs. Sylvia Henley; **J. B. Hunter**, C.B.E., M.C., F.R.C.S.; W. C. H. Luckett, J.P.; **W. G. Masefield**, M.R.C.S., J.P.

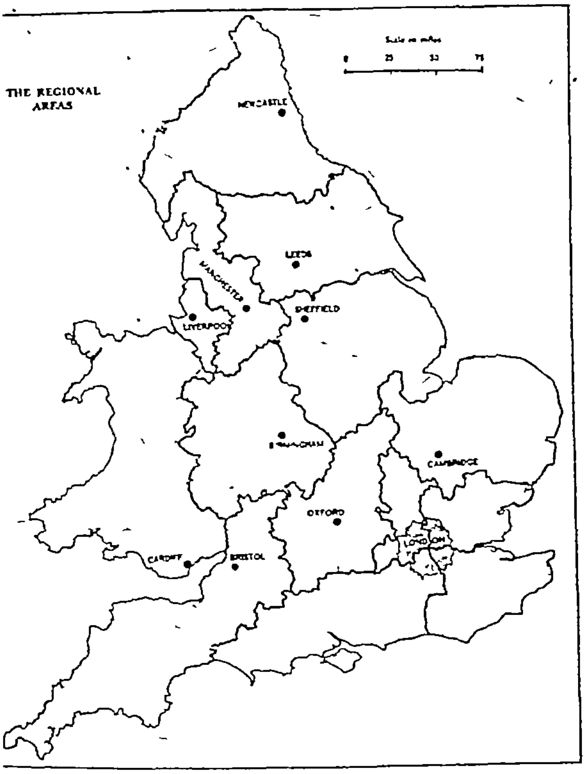
SOUTH-WEST METROPOLITAN REGION

Chairman: F. H. Elliott, D.L., J.P. (chairman, Surrey health committee).

(*a*) Alderman A. E. Allaway, J.P.; Alderman Colonel C. H. Gibson; **P. H. Mitchiner**, C.B., C.B.E., F.R.C.S.; J. A. Tulk, J.P.; **N. E. Waterfield**, F.R.C.S.; Sir Arthur Watson, O.B.E., J.P.; Alderman F. J. Woolley; **J. M. Wyatt**, F.R.C.S.

(*b*) Miss E. C. Batho; **Desmond Curran**, F.R.C.P.; Mrs. Helga Feiling; **C. B. S. Fuller**, M.C., M.R.C.P.; Miss P. Lee, M.B.E., S.R.N.; Alderman Alan Lubbock, J.P.; **M. F. Nicholls**, O.B.E., F.R.C.S.; J. L. Williams.

(*c*) **N. F. Adeney**, F.R.C.S.; G. E. Coke; E. F. Crundwell; Arthur Hague-Winterbotham; A. G. Linfield, O.B.E.; **G. H. Macnab**, F.R.C.S.; **D. Stark Murray**, M.B.; Richard Sargood, M.P., J.P.; George Thompson.



OXFORD REGION

Chairman : **A. Q. Wells,** D.M. (chairman, Oxfordshire alth committee).

(*a*) **E. C. Bevers,** F.R.C.S. ; Prof. **A. D. Gardner,** D.M. ; ord Henley, J.P. ; Alderman Mrs. Alice Jenkins, J.P. ; iss R. R. Jolliffe ; P. C. Raffety, J.P. ; A. J. B. Selwood ; **S. I. Skottowe,** M.D.

(*b*) **A. R. Banham,** F.R.C.S. ; Prof. **A. W. M. Ellis,** F.R.C.P. ; **S. Jones,** M.R.C.S. ; Colonel C. B. Krabbé, O.B.E. ; Miss osemary Spooner ; **J. A. Stallworthy,** F.R.C.S. ; Rev. J. D. urner.

(*c*) Miss Clara Adams, J.P. ; Sir Oliver Franks, K.C.B. ; M. Paterson ; W. R. Robins, J.P. ; Prof. **H. J. Seddon,** R.C.S. ; Miss **Janet Vaughan,** F.R.C.P. ; Alfred Woodley.

SOUTH-WESTERN REGION

Chairman : H. G. Tanner, J.P. (treasurer, University of ristol).

(*a*) Alderman Walter Barrett ; C. P. Brown, J.P. ; A. L. andler ; **R. E. Hemphill,** M.D. ; J. R. Makeig Jones ; **amuel McClements,** M.R.C.S. ; Alderman J. J. Milton, J.P. ; lderman Mrs. J. M. Phillips, J.P. ; **J. W. G. H. Riddell,** C., F.R.C.O.G. ; Miss R. C. Shackles.

(*b*) **C. T. Andrews,** F.R.C.P. ; A. C. Bowden ; Egbert adbury, D.S.C., D.F.C., J.P. ; Mrs. K. A. Goddard, J.P. ; ir Philip Morris, C.B.E. ; Brigadier Joseph Morrison, M.B.E. ; **William Niccol,** M.B. ; P. E. Russell ; Colonel H. B. Stokes, .B.E.

(*c*) Miss M. F. Awdry ; Prof. **R. J. Brocklehurst,** D.M. ; **J. Fuller,** F.R.C.P. ; G. G. Gilmour-White, O.B.E., J.P. ; . C. Morland : Mrs. Jacquetta Marshall ; Alderman H. G. Mason, J.P. ; Prof. **R. Milnes Walker,** F.R.C.S. ; Mrs. M. F. Williams.

WELSH REGION

Chairman : Sir Frederick Alban, C.B.E., J.P. (secretary, Welsh National Memorial Association).

(*a*) **R. D. Aiyar,** F.R.C.S.E. ; **A. H. Coleman,** O.B.E., F.R.C.S.E. ; Alderman E. A. Cross, M.B.E., J.P. ; **H. G. Davies,** M.R.C.S. ; Richard Davies ; Alderman Richard Gronow ; Alderman T. J. Kerrigan ; A. S. W. Johnson, J.P. ; Prof. E. A. Owen ; Mrs. Eleanor Owen ; Rev. B. Waldo-Lewis.

(*b*) Hubert Alexander, J.P. ; Alderman William Casey, J.P. ; **I. J. Davies,** F.R.C.P. ; T. P. Davies ; Alderman W. C. Davies ; Alderman Joseph Dicks ; Alderman J. J. Panes, O.B.E. ; Alderman **D. H. Pennant,** D.S.O., M.D. ; Prof. **O. H. Williams,** F.R.C.S.

(*c*) W. J. Canton ; Prof. **T. B. Davie,** F.R.C.P. ; **J. Lloyd** [illegible] ls ; Alderman Thomas Evans ; William Evans, J.P. ; Mrs. K. W. Jones-Roberts, J.P. ; Thomas McDonald ; Prof. **R. M. F. Picken,** M.B. ; **J. H. O. Roberts,** M.D. ; Alderman the Rev. W. D. Thomas.

BIRMINGHAM REGION

Chairman : R. R. Adam (chairman, Worcestershire health committee).

(*a*) Mrs. A. L. Barker ; **Norman Duggan,** F.R.C.S. ; Captain L. H. Green, M.B.E., J.P. ; Major Cyril Hotchkiss, J.P. ; Prof. **H. F. Humphreys,** O.B.E., M.C., M.B., M.D.S. ; **J. J. O'Reilly,** M.B. ; Sir **Leonard Parsons,** F.R.C.P. ; Arthur Smith, J.P. ; W. T. Smith, J.P. ; H. S. Waites.

(*b*) **J. A. Brown,** M.D. ; **L. A. Dingley,** F.R.C.S. ; E. T. Hobley ; Sir Ernest Johnson ; J. Latham ; R. E. Priestley, M.C. ; Miss Smaldon ; G. Alan Thompson ; Alderman L. Whitehouse, J.P.

(*c*) Alderman A. F. Bradbeer ; L. E. Bury ; Alderman W. L. Dingley ; D. J. Evans ; V. W. Grosvenor, J.P. ; C. O. Langley ; **J. H. Sheldon,** F.R.C.P. ; Prof. **A. P. Thomson,** M.C., F.R.C.P. ; **A. J. Watson,** F.R.C.S.

MANCHESTER REGION

Chairman : Sir **John Stopford,** F.R.C.P., F.R.S. (vice-chancellor, University of Manchester).

Members of boards may resign on giving notice to the Minister, and persons appointed to fill casual vacancies will hold office for the rest of their predecessors' term. If a board resolves that a member's conduct is prejudicial to the efficient performance of its functions the Minister may direct that he shall no longer be a member.

The boards may (and if so directed by the Minister shall) appoint committees, consisting wholly or partly of their own members, to exercise any of their functions, subject to such conditions as the Minister may impose. If, during six months, a member has not attended a meeting of the board or committee to which he belongs, the Minister (unless satisfied that his absence was due to illness or other reasonable cause) will declare vacant his seat on the board or committee.

The rules laid down for the conduct of meetings of regional hospital boards will apply also to meetings of boards of governors of teaching hospitals and of management committees. If the chairman refuses to call a meeting when six members ask him to do so they may themselves call the meeting. No business will be transacted unless at least a quarter of the members are present, and all questions will be decided on a majority vote of those present, the person presiding having a second or casting vote. The provisions of the Local Authorities (Admission of the Press to Meetings) Act 1908 (a) will apply.

EDWARD'S HOSPITAL FUND FOR LONDON

...e 50th annual meeting of the council of the Fund ...don on June 27 a message was read from the ... as patron, recalling that the Fund had been ...d by King Edward VII in 1897, to provide ...nal support for the voluntary hospitals at a time ...th ...culty and uncertainty.

... Duke of Gloucester, president of the Fund, said ...hen the distinction between the voluntary hospitals ...hose maintained by the local authorities was ended ...Fund would help both kinds of hospital. "The ...that in this great reorganisation the Fund remains ...to do its work in its own way is, I think, a mark ...blic confidence in its management." Grants, he ... had recently been made for travel; representatives ...Charing Cross Hospital had been enabled to make a ... continental tour to study hospital construction, with ...ew to planning the new Charing Cross Hospital to ...uilt at Harrow.

...r Edward Peacock, the treasurer, reported that ...l general receipts for 1946 amounted to £491,409, ...pared with £464,710 in the previous year.

...r. H. Morley Fletcher, chairman of the nursing ...uitment committee, said that the nurses' health-...ord forms issued by the Fund were selling at the rate ...0,000 a year. During the year over 4000 candidates ...training had been advised at the Nursing Recruitment ...tre. The Fund was, he said, continuing its annual ...nts of up to £5000 to group preliminary-training ...hools for nurses.

Sir Harold Wernher, presenting the report of the ...ergency bed service, said that 10,500 calls for help in ...ding a hospital bed for a patient had been dealt with ...ring the year—an increase of 55% over the preceding ...ar. The shortage of beds, even for urgent cases, was ...ore acute than ever, even though the London voluntary ...spitals had reopened since the end of the war no less ...an 3000 beds and now had only 15% of their pre-war ...mplement closed. "The overall shortage of beds," ...cording to the committee's report, "is so serious that ... point can be reached when no hospital, voluntary or ...unicipal, can take in a patient even when urgent ...rgery is required."

Sir Hugh Lett, presenting the report of the committee ...h hospital diet, spoke of the value of meetings which ...ad been instituted for catering officers. The standard ... feeding in hospitals in the King's Fund area was, he ...dded, definitely improving.

Sir Henry Tidy, chairman of the convalescent homes' ...ommittee, said that a directory of homes was being ...pared. The committee had assisted in the reopening ...es ...mes closed during the war.

...blic Health

Smallpox

...focus of infection is at Bilston, where ...s occurred during the past week. This ...ife of a patient removed on June 17, ...to hospital on June 29. She was vacci-... the time of her husband's removal. This ...had very few contacts. Unfortunately the same does not apply to the other Bilston family involved, from which 5 children were admitted to hospital on June 20 and 21. The diagnosis of smallpox is not confirmed in 4 other patients under observation.

Poliomyelitis

There was a further increase in notifications of poliomyelitis from 31 in the week ending June 14 to 44 in the week ending June 21. Some of these notifications were connected with the localised prevalences mentioned last week, but in addition small numbers were notified from all over the country except from the West and from Wales. There appears to have been a succession of cases in some localities. For example, in Ulverston, near Barrow-in-Furness, there were 7 notifications, falling roughly into five generations, between April 6 and June 21. Although notifications of polioencephalitis had not increased in the week ending June 21 (2 notifications), cases have occurred where the diagnosis between poliomyelitis and polioencephalitis has been doubtful.

Suspected Botulism

On June 6, 5 persons who had eaten lunch at a small tea-shop in the London area on the previous day noticed abdominal discomfort followed by obstinate constipation. Of these, 2 vomited, and all subsequently developed difficulty with vision, and/or speech and swallowing. 1 man died on the twelfth day, and some still have signs of poisoning with a persistent neurotoxin involving the brain stem. 2 have remained ambulant throughout. Although the origin and nature of the poison are still under investigation, a tentative diagnosis of botulism has been made and preventive action taken. It is not improbable that several, perhaps half a dozen, other persons were involved, and this note may help practitioners to make a retrospective diagnosis: ptosis, fixed pupils, and diplopia may still be present. The attention of medical officers of health should be called to suspicious cases.

Notification of Puerperal Fever in London

Whereas puerperal pyrexia is notifiable both in London and the provinces, puerperal fever is notifiable in London only. Here the regulations are confused: the separate notification of puerperal fever has been found to serve no good purpose, and the resulting statistics have proved valueless. The London County Council's hospitals committee has therefore suggested that the Public Health (London) Act, 1936, should be amended by the removal of puerperal fever from the list of notifiable infectious diseases.

Infectious Disease in England and Wales

WEEK ENDED JUNE 21

Notifications.—Smallpox, 7; scarlet fever, 870; whooping-cough, 2107; diphtheria, 220; paratyphoid, 11; typhoid, 7; measles (excludng rubella), 10,632; pneumonia (primary or influenzal), 328; cerebrospinal fever, 39; poliomyelitis, 44; polioencephalitis, 2; encephalitis lethargica, 2; dysentery, 47; puerperal pyrexia, 121; ophthalmia neonatorum, 64. No case of cholera, plague, or typhus was notified during the week.

The 7 cases of smallpox were notified at Bilston, Staffs.

Deaths.—In 126 great towns there were no deaths from enteric fever, 1 (1) from scarlet fever, 2 (1) from diphtheria, 7 (1) from measles, 13 (3) from whooping-cough, 78 (1) from diarrhœa and enteritis under two years, and 1 (0) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 258 (corresponding to a rate of 26 per thousand total births), including 25 in London.

Modern Care of Old People

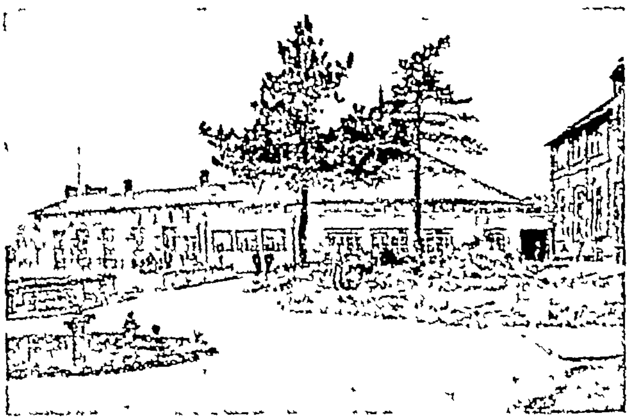
VI

MUNICIPAL INSTITUTIONS

Birmingham's Example

BIRMINGHAM'S provision for the old includes four large homes, administered by the public-assistance committee, for those requiring no special medical care. Of these four, housing altogether 831 people, one was used during the war as a hospital but is to be reopened next month. A fifth, and rather more elaborate, home is planned; this will be self-supporting at a cost to each occupant of about 50*s.* a week. The average cost of each person in the existing homes is 32*s.* 4*d.* a week; and each is expected to contribute according to his means. Those who can afford no contribution are maintained without charge; those with means, however small, retain a small amount for personal use; while those over 65 years and without means are provided with pocket-money.

Two of the homes are for men and two for both men and women. The committee is convinced that there is a place for such mixed homes; these even include suites for married people, which surprisingly are not in great demand.



Dining-hall and new block.

ARRANGEMENTS FOR MEN

Before going to one of the other homes, men spend a few days in a receiving home, with 101 beds, while the superintendent decides which home will best suit them; and where possible, the new entrant goes to the home he chooses. Though nominally simply a receiving centre, this home also retains some who want to remain, besides the very few who have given trouble at the other homes. If, after observation, a man continues to be troublesome he is admitted to an infirmary; but this is necessary in only one or two instances each year.

QUINTON HALL

The principal home for men is at Quinton Hall, on the outskirts of the city. Here a former theological college, surrounded by lawns and open fields, has been adapted and extended to take 310 old people. Linking the old with the new block is a large octagonal dining-hall, containing a stage for concerts and furnished with tables for 6 and 12.

Sitting-rooms and dormitories occupy the rest of the ground floor. About one in three of the residents is incapable of climbing stairs, and needs a ground-floor bed. The dormitories vary in size, some containing as few as 4 and others as many as 30 beds; but the committee proposes to subdivide the larger rooms.

Each man has his personal locker, which is soon to be replaced by a full-length wardrobe. New clothes are issued where necessary, but uniform is shunned; each man has his own three sets of underclothing. The paint is war-worn and rather drab in colouring; but it is being renewed in fresh light colours as quickly as supplies permit. White bedspreads, though they look rather bleak, have been deliberately chosen, because the first signs of soiling are easier to detect on white than on coloured materials. Pastel shades, however, show soiling nearly as quickly, and give a pleasanter look to a ward or dormitory.

The bathrooms contain a simple and effective device for helping old people to raise themselves in the bath: a cross-bar is attached to the end of a rope suspended from the ceiling. Some years ago hand-rails were fitted throughout the corridors; the less able get along by gripping the rail with one hand and a stick with the other.

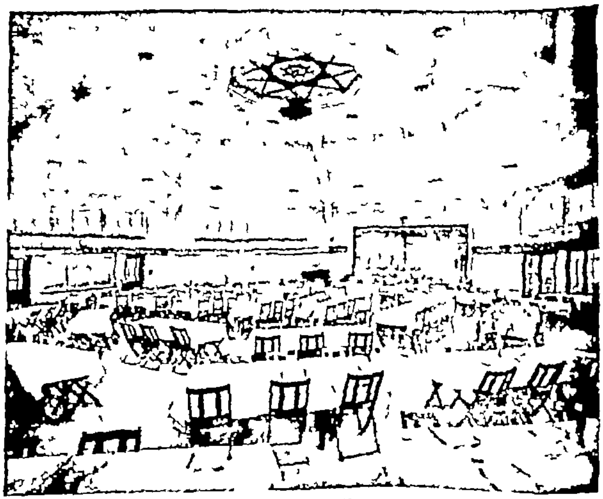
SITTING-ROOMS AND RECREATION

Leading off the ground-floor corridor is a series of airy sitting-rooms, containing from 20 up to about 80 chairs; the larger rooms are shortly to be divided to give a more intimate atmosphere. These too are to be decorated in light colours as soon as possible. Experience with different chairs has shown that most of these elderly people favour a straight-backed wooden armchair, with or without a head-rest; low divans and easy chairs, which are also provided, are preferred by some of the more agile residents.

For entertainment, besides concerts in the winter, there are a billiards-room, a large library, cards, various other games, and a bowling-green. The superintendent and matron retail sweets to the residents, and use the profits for prizes in competitions. In the summer a cricket team, organised by the visiting doctor and superintendent from the staff and others, plays once a fortnight in the grounds and attracts an enthusiastic following.

ADMINISTRATION

There are only two rules: the old people are expected to attend promptly at meals and to be in bed normally by nine o'clock. Though the bedtime rule needs no enforcement (indeed many go to bed after their tea at 4 o'clock, without waiting for supper) and though residents may, if they tell the superintendent beforehand, come in or go to bed later, the principle of a fixed bedtime is perhaps a little at variance with the sense of liberty which the Ministry of Health wishes to encourage in such homes, especially as everybody over sixty has been in the habit of choosing his own bedtime ever since he grew up. During the day residents



Dining-hall.

can come and go as they will, however, and they can receive visitors at any time.

Work is not forced on the residents, but those who like can garden or undertake other useful tasks; and a workshop is to be opened. There is no question of training them in profitable crafts, for their average age (though lowered by one or two cripples in the forties) touches 75; but it is thought that, even if they do not make much, they may like to use their hands and to have the workshop as an additional social centre. In the last few years the age at entry, and thus the average age, has been creeping up, perhaps because men of 65–70, who would formerly have been retired, have been retained in industry.

There are few complaints, except about the price of tobacco; and this is not peculiar to a home for the old. The work is not easy for those in charge: it calls for patience and understanding, some firmness, and above all a feeling that the job is worth doing. Regular visits are paid by members of the public-assistance committee; but they recognise that the atmosphere of the home is made by the superintendent and matron: and since these have been hand-picked the atmosphere is very happy. These officers are so carefully chosen that the committee often has difficulty in finding suitable people even among a large number of applicants.

THE PSYCHOLOGY OF AGE

For an elderly person entry to any institution is a big step, taken with considerable fear and foreboding. At the reception home small dining-room tables for four have proved their value, for if a lonely newcomer is uncomplainingly disinclined to eat the other three at his table immediately notice and pass on the news to the matron. Tables are rather larger at Quinton Hall, since each man eventually attaches himself to a group, which forms a small community in itself; and on first arriving every man is placed under the charge of an older inhabitant until he has established himself.

For those who have reached 75 it is a shrinking world, often bounded on the one hand by sleep and on the other by food. In between these two the demand is principally for comfort and freedom from irritating restrictions. In the Birmingham homes these wishes are satisfied.

Reconstruction

THE DOCTOR'S PENSION

SUPERANNUATION UNDER THE ACT

THE draft regulations [1] which we noticed briefly last week set out a contributory superannuation scheme for—

(a) Officers and servants of regional hospital boards, executive councils, and other bodies constituted under the National Health Service Act.

(b) General medical practitioners, and general dental practitioners on the lists of executive councils.

(c) Other persons engaged in health services, whether provided under the Act or otherwise.

The scheme, which will be administered by the Minister of Health, will be financed by contributions from the participants and from Exchequer moneys. The major benefits are a pension and a lump-sum retiring allowance, together with a widow's pension. Subsidiary benefits include a death gratuity, an incapacity pension, an injury allowance, a short-service gratuity, and an option to a pensioner to allocate part of his pension to his wife or any dependant.

Provision is made for preserving rights in respect of previous superannuable service, and superannuable employment in the central health service is made interchangeable with superannuable service in the civil service, local government service, and teaching service. "The scheme also extends and modifies the Local Government Superannuation Act, 1937, . . . by substituting benefits similar to those provided by the draft regulations for the benefits of the Act of 1937. . . . Similar provision is made in relation to the superannuable staff employed by local education authorities for the purposes of the school health service."

The scheme is comprehensive in that there can hardly be any health worker accepting whole-time or part-time employment in the new service who does not fall into one of the three categories (a), (b), or (c). Included in them will be doctors, dentists, nurses, midwives, physiotherapists, hospital technicians of all kinds, lay administrators, almoners, clerical and domestic staffs, and many types of manual worker. The great majority will be paid by salary, directly or indirectly by the hospital board, or the executive council, and will come into category (a). The doctors and dentists under contract with the executive council will be paid differently, their remuneration being made up of capitations, or fees for items of service, both of which may vary widely from year to year; they are therefore placed in a different category, (b), with a different scheme for the assessment of benefits. The chief beneficiaries under (c) are local-government officers and officers of the school medical service for whom special provision is made though they do not become direct employees of the central authority.

The contributions payable by the "employee" and "employer" respectively are 6% and 8% of the remuneration (except for manual workers where it is 5% and 6%). In the case of practitioners, an allowance for expenses, assessed according to a formula to be laid down by the Minister, will be subtracted from total remuneration before the percentage levy is made. A principal employing an assistant in general practice will have to pay the employer's contribution in respect of his assistant. Anyone who resigns or is discharged from the service before becoming entitled to pension or other benefit will (except if his resignation or dismissal is in consequence of fraud or misconduct in connexion with the performance of his duties) be entitled to a return of his contributions plus compound interest at 2½%.

MAJOR BENEFITS

Pension.—In categories (a) and (c) the amount of pension is for each year of contributing service one-eightieth, and for each year of non-contributing service one-hundred and sixtieth of the average remuneration (defined as the annual average of the remuneration for the last three years of employment). The maximum pension is to be forty-eightieths of the average remuneration. In category (b) the pension is for each year of contributing service 1½% of the remuneration for that year. Should there be more than 40 years' contributing service only the last 40 years can be counted.

Lump-sum retiring allowance.—This immediate payment on retirement amounts to the equivalent of three times the annual pension earned, but only a third of this is payable "in the case of a married male officer in respect of whose service a widow's pension may become payable."

Widow's pension.—This amounts to a third of the pension the officer was receiving when he died, or would have received had he retired on the day before his death.

This represents a considerable advantage over previous schemes (including some applicable to Government servants) where the pensioner's benefits ceased entirely on his death, and his widow was left with no continuing remuneration.

The widow's pension is subject to increase should she be older than her husband, or decrease should she be younger, on an actuarial scale included as a schedule in the draft regulations. "A widow's pension shall cease to be payable to a widow if she remarries, or in respect of any period during which she is cohabiting with a man as his wife."

---

[1] H.M. Stationery Office. Pp. 88. 1s. 1d.

SUBSIDIARY BENEFITS

Death gratuity.—This is the equivalent of the retiring allowance, and is payable to the officer's legal personal representatives should he die before reaching retiring age. Again the amount is equivalent to three years' pension as then accruing, and again it is reduced by two-thirds if a widow's pension is payable.

Incapacity pension becomes payable if an officer is no longer employable by reason of permanent ill health or infirmity of mind or body. In amount it is the same as the retiring allowance.

Injury allowance is payable if an officer ceases to be employed in consequence of permanent incapacity due to an injury sustained in the discharge of his duty. This is a variable sum not exceeding two-thirds of his annual average remuneration.

Short-service gratuity.—This, which is payable to an officer who has to retire through ill health before becoming entitled to an incapacity pension, amounts to one year's "average remuneration."

QUALIFYING PERIODS

The periods of service which have to be completed before the above benefits are payable are as follows:

Pension.—Ten years' service, on or after reaching age of 60 (55 for mental-health officers, female nurses, physiotherapists, midwives, and health visitors).

Retiring allowance.—Five years' service, on or after age of 60 (or 55 for categories as above).

Widow's pension.—Ten years' service.

Death gratuity.—Five years' service.

Incapacity pensions.—Ten years' service.

Injury allowance.—No qualifying period needed.

Short-service gratuity.—Five years' service.

OTHER PROVISIONS

Ordinarily if a pensioner after retiring accepts other work remunerated from public funds his total remuneration from pension and earnings may not exceed the annual "average remuneration" as assessed when his pension was granted. Should it do so, the pension will be reduced accordingly. This proviso is waived in the case of practitioners receiving pension who continue to practise between the ages of 65 and 70. If they continue to practise after 70 it becomes operative.

Those doctors or nurses at present included under superannuation arrangements such as those of the Federated Superannuation System for Universities or the Federated Superannuation Scheme for Nurses and Hospital Officers may if they so request continue in their present scheme (the Government taking over the employer's responsibility) and not transfer to the new scheme. Similar arrangements are allowed to local-government officers, who need not transfer to the new scheme unless they so wish. There seem, however, to be some advantages which will induce some of these officers to transfer—not the least being the opportunity they are given to opt to make payments which will allow a period of non-contributing service to be reckoned for pension as if it had been contributing service.

Practitioners in contract with executive councils who have already entered into commitments with life-assurance companies may opt out of the superannuation scheme and receive instead the 8% of their remuneration (ordinarily set aside as the Exchequer contribution to superannuation) for use to help to pay their insurance premiums.

Another useful provision allows the Minister to direct "if he is satisfied there are exceptional reasons for so doing" that in the case of late entrants into the scheme (e.g., a person who becomes an officer of an employing authority after attaining the age of 35) the years of service for calculating benefit may be treated as eight-fifths of the actual years served.

Finally it appears that every effort has been made to ensure that no bar or difference between superannuation provision in the different parts of the future medical service shall remain to hinder the free movement of members of the service from district to district, or from one branch of the service to another. Movement from general practice to part-time or whole-time specialism, from clinical to academic medicine, from teaching to research, from local-authority to central-authority service, are all foreseen and facilitated.

The architects of this very complicated, and at many points entirely unprecedented, scheme, have tackled their task courageously and with no small measure of success.

Medicine and the Law

Overdose of Proprietary Medicine

AT an inquest in Manchester on June 24, evidence was given that a $2^1/_2$-year-old boy had died after drinking half of a bottle of a proprietary medicine which was said to have contained in all about one grain of morphine. The medicine, known as 'Johnson's Celebrated Infants Preservative,' had previously been given by the dead boy's mother to another (infant) son for the relief of flatulence. "It seems to me criminal," said the deputy city coroner, "that this sort of thing is sold indiscriminately to parents who are not told that it can be just as poisonous as carbolic acid." He returned a verdict of death through misadventure by morphia poisoning.

Another Missing Swab

The death of a woman last April at a maternity hospital after a cæsarean section was the subject of a recent inquiry in the Paisley sheriff court. A post-mortem examination disclosed the presence of a swab measuring 24 × 8 inches in the body. Death was due to peritonitis.

The hospital routine was described to the court. After an operation, and before the wound was stitched, the nurse who had been handing out the clean swabs had to check the soiled swabs which had been collected by two other nurses, so that she could see that all were accounted for. Then she had to report to the nursing sister—in this case the matron—who in turn had to report to the surgeon if any swabs were missing. After the operation last April the nurse reported three swabs missing. The matron told her where she would find two of them; these two were then retrieved. The matron omitted to report to the operating surgeon that one swab was missing. The sheriff observed that the matron had failed in her duty. There was evidence that she was feeling overworked after a long period of physical strain; but the whole system of checks which the hospital very properly insisted upon, and which it was her duty to see enforced, had been laid aside.

In very similar circumstances recently an English coroner placed a share of the liability upon the operating surgeon. It is interesting to note that Sheriff Hamilton at Paisley made no such suggestion.

CHILDREN WITH DEFECTIVE SPEECH.—On June 28 Mr. G. Tomlinson, Minister of Education, opened Moor Hurst School at Hurst Green, Surrey, which is the first school in the country for children with speech defects. The West End Hospital for Nervous Diseases bought the house with funds raised from voluntary sources after discussions between the Ministries of Health and Education in 1943, at which Sir Harold Gillies urged the need for intensive speech training for children who had been operated on for hare lip and cleft palate. Originally intended for these children, the school has also admitted aphasic children who are unable to speak, although not deaf. At the formal opening Mr. Tomlinson said that local education authorities needed a further 150 speech therapists for the 75,000–100,000 children requiring treatment.

In England Now

A Running Commentary by Peripatetic Correspondents

THE illegal immigrant ships still come in. My job is merely to minister to the medical wants of the troops guarding the dock area, a task which resolves itself into sitting in the back of my ambulance and keeping brother officers away from my small stock of "medical comforts." So far my only patient has been a private soldier who drank half a beer-bottleful of urine under the impression that it contained its original commodity, a sad reflexion on somebody—probably on those who make the beer rather than the thirsty victim. Those M.O.'s who run the R.A.P. on the wharf itself see some cases—hysterical immigrants with pains in various places; and sometimes as many as half a dozen pregnancies which provide them with an opportunity for discovering how difficult it is to distinguish a breech from an occiput. The troops do their job well, maintaining a remarkable patience in marshalling the queues to go into the searching tents, considering how long they have been standing by before the ship even comes into dock. "Come on, Miss, this way. Its your birthday today!" and "Keep in line, there's no hurry; you'll all get your turn!": this last a bit cynical. The immigrants—at any rate by the time they reach port—are mostly well behaved, and their philosophical acceptance of the searching of their baggage and their persons, and the squirting of D.D.T. powder inside their clothes, seems to indicate a sadly long apprenticeship in being on the wrong side of officialdom.

* * *

It is very difficult to decide what to do when one sees a case where the diagnosis has been missed by somebody else. I mean cases where a hospital or consultant of repute has seen the patient recently and it is obvious that the disease is not a new development but was genuinely overlooked through some omission in the history-taking or examination. It looks so conceited if one writes to a consultant to tell him where he slipped up. No-one has ever written to me telling me of some howler which has been discovered at another hospital, but I have no doubt that at hospitals all over the country patients whom I have misdiagnosed are being set right. Disseminated scleroses are having their spinal tumours removed, presenile dementias are having malarial therapy for G.P.I., and fibrositises of shoulders are having their carcinomas of bronchus investigated. I suggest a central bureau for bricks, to which everyone would send reports of howlers they had uncovered. The sinner would then receive a tactful note from the bureau explaining that such and such a case treated by him for inoperable carcinoma of the stomach was a classical pernicious anæmia, now quite well on liver treatment, thank you. There would be no mention of the hospital or consultant responsible for the discovery. I have seen a lot of motes in other people's eyes recently and I wish I could be told about some of the beams in my own. No marksman has a chance of hitting the bull consistently unless they signal from the butts to show where the wide shots have landed, and I would like to hear about some of my magpies and outers. Poor fellows, I hope they're doing better now.

* * *

Tempora mutantur et nos in illis. How great the changes are was lately driven home when the specialist decreed that my convalescence would be hastened by arm-swinging and breathing exercises. The prescription caused me some dismay, for the last occasion on which I was let in for organised physical training was during the 1914–18 disturbance. The first session was an agreeable surprise (session is the right word, for we sat on stools which eased the situation a good deal), and the exercises, methods, and aims were all new to me.

The even precision of the old drill methods has been replaced by the loose smooth rhythm of easy movement. The only reference the instructor made to muscles was to tell us to loosen them and relax: we were told "unscrew your head slowly and then screw it back on again and never mind the creaks." His emphasis was on the circulation and on giving the lungs sufficient room to work.

Some simple coördination exercises hit the class in a weak spot. It looks easy enough to stick out opposite legs and arms first forwards and then sideways, but in practice our class would have been a howling success on any music-hall stage. The proceedings were held up more than once by the almost hysterical laughter of those in the back rows (I was in front). More exercises were done lying on a mattress (an excellent idea, I felt), and then we graduated to rhythmic contortions with broomsticks and medicine-balls. After the first two days I thought my rectus femoris would never be the same again, but this rapidly passed and I began to enjoy the sessions thoroughly. Moreover I was agreeably astonished by the speed of my recovery. The instructor certainly knew his job, and not only on the technical side—he had a tactful yet stimulating "gym-side manner" which won the support of our collection of crocks.

It seems to me that in general practice far greater use should be made of simple exercises in convalescence, and that would mean much wider opportunities for such therapy. The exercises must be done under skilled direction, or they will certainly be useless and may be harmful. Perhaps it will be possible to organise something of this kind in connexion with the health centres.

What is being done in medical schools today to instruct students on the uses and limitations of physiotherapy? In my own medical school all we had was a few lectures on massage—and even that was unusual at the time. Until I sampled modern exercise therapy myself and saw its effects on the other patients I had no idea either of its efficacy or its scope. I don't suggest that every student should become an expert physiotherapist but he should learn enough to pass appropriate cases to the expert with proper instructions.

* * *

For some time I have been carrying out a health survey in industry which necessitates asking uncomplaining subjects a lot of personal questions. On the whole my questionees have answered with great good will, but as it seems only fair to let them have a go at me after I have cross-examined them, I usually end the interview by saying, "Now I have asked you a lot of questions is there anything you would like to ask me?" Often there isn't, but sometimes there is, and just occasionally I get properly caught. A few days ago, when for the thousandth time I asked my usual formula, the man looked at me for a moment, then answered, "Yes, will you join me in a pint?" It was fortunate that I had already got most of the day's work done, for it was several hours before I got back to see the next patient.

* * *

I am no longer peripatetic. A cellulitis has immobilised me as completely as even my enemies might desire. But the mind still has its flights of fancy, and as I chew my own particular brand of sulphonamide tablets, I speculate on whether the streptococcus or the granulocytes will *pack up first.* *Yesterday it was anybody's guess.* Today the enemy wavers and the turning movement seems likely to come off.

Are people ever threatened with an illness? Probably they've either had it or they haven't, but there must be a time when it begins if one can only mark it. On Sunday at 10 P.M. I cracked my elbow—both it and the skin—and I was quite well until 5.30 P.M. next day, when I suddenly felt exhausted. Half an hour later the arm was painful and I knew that the fight was on because of the sense of exhilaration. A few months ago a peripatetic correspondent described the euphoria which often marks the beginning of a head cold. I have had that all my life, and for a few glorious hours at these times of impending misery I feel really efficient. Normally I have little or no sense of smell but it comes back with the euphoria and I recapture delightful associations. So it was when the cellulitis started.

As I lay yesterday ruminating on the prospects of victory I received a wire from the Editor asking for a note on an old friend who has passed on. I knew him well, liked him, and was in a position to appraise his work—but suppose I hadn't liked him! It's a sobering thought. The streps are putting up a stout rearguard fight. I must make a note to book *my* reviewer.

Letters to the Editor

THE STUDENT AND THE ALMONER

Sir,—If students are to gain any insight into the social problems uncovered by regarding the patient as a human being with family, living, and income-earning problems, some way must be found of introducing them under expert guidance into a large number of homes.

Hospital almoners are already overworked; but physicians on hospital teaching staffs can stimulate interest through the questions they put, and their comments; and midwifery on the district often makes the more imaginative aware for the first time of aspects untouched by the writers of textbooks. I am, however, convinced that a month spent with a general practitioner who took the students into such homes as he could, and who discussed other cases as he went round, would be the most valuable method. I should like this training inserted between the final examination and qualification. Those of us who teach must be aware of a certain impatience among students towards knowledge that does not help in examinations; but when these are passed there is a swing-over towards practical knowledge.

Both practitioner and student would find the experience entertaining and illuminating. There are difficulties, as Dr. Harding (June 21) says; but the plan is feasible.

London, N.W.1. S. R. Eastwood.

SUCCESSFUL REVACCINATION

Sir,—Dr. Geoffrey Edsall's letter of June 21 will be of great interest to many of your readers, and his theses as to the interpretation of the reactions to vaccination seem to be sound. They do not, however, provide a solution to the problems that concern the quarantine officer in practice, and Dr. Edsall's contention that a "nil" reaction should not be accepted (no matter how many failures to take the patient has already experienced) is not a practical proposition for those who wish to travel—particularly if they wish to travel in some haste.

The United States authorities have recently laid down that no person shall be admitted to the States from this country unless he can produce a certificate of successful vaccination performed within the last three years. This, following Dr. Edsall's contentions, has the effect of excluding certain people, including myself, from any possibility of going to the United States.

I was vaccinated in infancy with four criss-cross insertions, the scars of which are still clearly visible. I was revaccinated on the opposite arm by exactly the same method at the age of twelve and took successfully. Since then, though I have been revaccinated on many occasions, I have never had the slightest suggestion of a take, and the so-called immunity reactions have been barely perceptible. On the last occasion that I came into contact with a suspected case of smallpox, only a few weeks ago, I decided to be vaccinated as brutally as possible—that is, by four large insertions (two on one leg by the criss-cross method, two on the other leg by multiple puncture) using fresh lymph obtained from the Government laboratory. A few hours afterwards I had a slight trauma reaction, which rapidly cleared up, but no sign whatsoever of any take or immune reaction.

Dr. Broom would certify me as "insusceptible to vaccination," which seems a reasonably good description of the state of affairs, but which I take it does not necessarily mean that I am immune to an attack of smallpox, though the fact remains that I have seen and handled a number of cases of smallpox in recent years and have not been attacked.

What is to be done from the point of view of travel and immunity from quarantine measures for people who, like me, fail to take? We do not object to a reasonable amount of revaccination, though it is a bit of a nuisance to have to be revaccinated every eight days for an indefinite period. What is more serious is the risk that we run, in leaving the country, of having to submit to "surveillance," or possibly to revaccination with a doubtful lymph applied by methods that may not be above criticism, or even of being refused permission to embark, or to land, because we have not a certificate of successful vaccination.

If Dr. Edsall can suggest an alternative to the te "insusceptible" in such cases, or suggest some int national agreement whereby after, say, three unsuccess revaccinations the vaccinee will be exempt from furt vaccination and from all quarantine measures, he be rendering us a good service. Even then the vacci would have to wait 24 days before embarking, by or air, for say the U.S.A. You will appreciate, Sir, serious effect on travel and commerce of su impedances.

The fact is that we are a non-immune population, considerable risk of invasion by smallpox, and have only ourselves to blame for it. While can do what we like with our people, we must whine if other countries dislike our practices and precautions.

It is up to the authorities to decide how to protect if not from smallpox, at least from serious interferen with our liberty to travel and to trade.

CONSENT TO DEATH

Sir,—In your annotation of June 7 you quote fr Dr. Harry Roberts's book, *Euthanasia and other Asp of Life and Death*, published in 1936. In the pass quoted, Dr. Roberts criticises as being unduly complicat the procedure given in the first draft of a Bill wh followed suggestions made in my presidential addres the Society of Medical Officers of Health. May I po out that the provisions of the Bill sponsored by t society which I represent, and introduced into the Ho of Lords by the late Lord Ponsonby, are much l complicated. There is no reference to a magistra the nearest relative does not have to be informed, a there is no delay of seven days. Practically all of I Roberts's criticisms have therefore been met.

C. Killick Millard
Hon. Secretary, Voluntary Euthanasi
Leicester. Legalisation Society.

COLD AGGLUTININS IN ATYPICAL PNEUMONI

Sir,—I was associated with Dr. G. E. O. Williams part of the work on cold agglutinins in atypical pne monia, which he reported in your issue of June 21 (p. 86 and would like to make a few comments.

Dr. Williams's views on the ætiology of cases with hig titres are strongly supported by the work of Eat and others.[1] They have isolated a virus from cases atypical pneumonia, grown it in the chick embryo, an transmitted it to cotton rats in which it produces a pneumonic illness. Serum from cases in convalescence, but not in the acute stages, protected the rats from infection (the basis now of a diagnostic test[2]). They found high cold-agglutinin titres in 12 out of 16 cases from which the virus had been isolated.[3] Such titres have been described in several outbreaks of atypical pneumonia,[4,5] whereas apart from trypanosomiasis they are uncommon in other infections (note especially Finland's[5] series of over 800 controls). It is difficult to resist the conclusion that most cases of atypical pneumonia with high cold-agglutinin titres are due to a specific virus.

The common radiological findings of mottling and patchy consolidation in Dr. Williams's cases with high cold-agglutinin titres might have been predicted from the findings at post mortem in a case from whom Eaton and others[2] isolated the virus. The lung contained nodules, discrete in some areas, confluent in others. The pleura over superficial nodules was inflamed.

Stimulated by Dr. Williams, I set out to determine the *clinical* picture presented by infection with the *supposed* virus, taking 1 : 128 as a diagnostic cold-agglutinin titre. I was able to collect only 12 cases. Nevertheless the case-records are similar to one another and to 16 cases from which the virus had been isolated described by Eaton and others.[3] I would therefore like to sketch tentatively what I suspect to be the picture of the

2. Eaton, M. D., van Herick, W., Meiklejohn, G. *Ibid*, 1945, 81, 329.
3. Meiklejohn, G., Eaton, M. D., van Herick, W. *J. clin. Invest.* 1945, 24, 241.
4. Meiklejohn, G. *Proc. Soc. exp. Biol., N.Y.* 1943, 54, 181.
5. Finland, W. et al. *J. clin. Invest.* 1945, 24, 451 (see also Dr. Williams's references).

ncomplicated disease. It appears to be essentially a lmonary infection. Upper respiratory symptoms are onspicuous—a helpful point in the clinical distinction m mild influenzal bronchopneumonia. Onset is with nstitutional symptoms and a dry cough; muco- rulent sputum appears later. Diminished resonance d breath sounds and showers of râles are almost ariable. Pleuritic pain, pleural friction, and localised ns of consolidation do occur but are uncommon nsistent with the morbid anatomy above). Herpes rilis occurs less commonly than in bacterial pneu- onias. Splenomegaly is not a feature (compare other ms). The disease is usually mild and prognosis good, t severe cases may occur with prostration, dyspnœa, anosis, and death.

Finally a note on the intriguing association of atypical eumonia, high cold-agglutinin titres, and hæmolytic æmia.[6] A prima-facie case has been made out for their usal relationship. If confirmed, the finding of hæmo- tic anæmia in atypical pneumonia will surely be almost thognomonic of infection with this virus.

North Middlesex County Hospital. D. FERRIMAN.

HYPOPITUITARISM AND ANÆMIA

SIR,—Writing in THE LANCET of May 10, Dr. Watkin- n, Dr. McMenemey, and Dr. Evans describe 2 cases hypopituitarism and anæmia, and their treatment with stosterone. This very interesting article has tempted s to record a similar case which appeared to be benefited y testosterone.

A married woman, aged 57, was admitted to hospital under e care of Dr. Richard Clarke, complaining of a feeling of eakness, lethargy, and cold for about a year. She had been althy in childhood and early adult life. Her first child was illborn, but at the age of 34 she gave birth to a child who still living. Her third pregnancy, at the age of 37, was mplicated by slight antepartum and severe postpartum æmorrhage; the child was stillborn. Thereafter the menstrual eriods, previously regular, became irregular, and the meno- ause came on at the age of 40. She said that she had never een really well since the last stillbirth. During about the ast year, in addition to lethargy, which at one time was so evere as to confine her to bed for six weeks, "too weak to ove," she had felt the cold bitterly, had attacks of numbness n the fingers, and latterly had some difficulty in walking. here was no recent loss of weight, but she had been very ight for some time. Appetite was fair.

The patient's height was 5 ft. $0^1/_2$ in. and her weight 7 st. he was slow in movement and in speech, with a dry cracked oice. The skin was fine but dry, the cranial hair thin and canty, and the nails poorly formed. Axillary and pubic air were completely absent. The only abnormal pigmenta- ion, on the front of the shins and very patchy, bore indirect estimony to her sensitivity to cold. The tongue was smooth nd glazed, and clinically she appeared anæmic. No abnor- nality was found in the cardiovascular or respiratory systems. he blood-pressure was 100/70 mm. Hg. There was an exag- erated lumbar lordosis and dorsal kyphosis. The gait was lightly spastic; there was increased tone in the left leg; nd the left plantar response was extensor. There was some yperæsthesia of the feet, but no sensory loss or ataxia.

The anæmia proved to be normocytic and hypochromic: ed blood-cells 3,200,000 per c.mm.; Hb 7·7 g. per 100 c.cm.; olour-index 0·9; P.C.V. 29·5%; M.C.V. 92 c.µ; M.C.H. 24 γγ; .C.H.C. 26%; reticulocytes 0·4%. Bilirubin less than 0·2 mg. er 100 c.cm.; plasma sodium 290 mg. per 100 c.cm.; blood holesterol 135 mg. per 100 c.cm.

X-ray examination of long bones and spine showed dimi- ished calcium content; the sella turcica was within normal imits.

A gruel test-meal showed complete achlorhydria, but free cid appeared after the injection of histamine. The capillary lood-sugar before and at quarter-hourly intervals after ngestion of 50 g. glucose was as follows: before glucose 75 mg. per 100 c.cm.; after glucose 100 mg., 140 mg., 145 mg., and 160 mg. per 100 c.cm. After injection of 10 units of insulin ntravenously the blood-sugar fell to 24 mg. per 100 c.cm. in half an hour without symptoms of hypoglycæmia. The 24-hour excretion of 17-ketosteroids was 0·8 mg., and the Kepler test was positive in both procedures.

Sheehan[1] has described many cases of hypopituitarism in women following hæmorrhage at childbirth; some of them had severe anæmia. One of the cases with anæmia complicating hypopituitarism described by Snapper et al.[2] was in a woman who had suffered a postpartum hæmorrhage. The case we have described we believe also to be one of hypopituitarism, due to partial necrosis of the anterior pituitary after postpartum hæmorrhage. Hypopituitarism has in this case, as in those of Snapper, and Watkinson et al.,[3] been associated with anæmia and achlorhydria. Unlike the cases of Snapper, but like those of Watkinson, the blood condition of our patient failed to respond to iron, thyroid, and liver, and her general condition remained stationary and apathetic.

Before the war one of us (G. L. F.) was impressed clinically by the plethora, increase in weight, and raised basal metabolic rate (B.M.R.) occurring after some weeks, in females treated with testosterone. Reports have since been published of a number of cases of Simmonds syndrome treated with androgens, which produced increase in weight, increase in B.M.R., and nitrogen retention, along with general clinical improvement.[4 5 6 7] In only one of these papers[4] was the blood picture discussed; and in this it was reported as unchanged.

From clinical experience, however, it was decided to try testosterone in our case; and since its addition to the therapy an improvement in the clinical and hæmatological condition has been observed. From the first the patient was given ferri et ammon. cit. gr. 90 daily, 'Anahæmin' 2 c.cm. twice weekly, 'Benerva' 25 mg. daily, and thyroideum siccum. The thyroid, started cautiously with gr. $^1/_4$ daily, was gradually increased until, 45 days after admission, she was receiving gr. 2 daily. There was, however, very little progress, and on the 27th day six 100 mg. tablets of testosterone were implanted subcutaneously, and before discharge she was transfused with two pints of packed red cells. She was later given methyl testosterone 15 mg. daily, absorbed through the sublabial mucosa, and when seen as an outpatient on the 76th day she had improved clinically and had more energy. Her blood-pressure had risen to 160/100 mm. Hg, but the weight was unchanged.

A month later she was very definite that subjective improvement had occurred. Her blood-pressure was 140/90 mm. Hg, and some pubic hair had appeared. The implanted tablets were still palpable. Red blood-cells 4,900,000 per c.mm., Hb 88%, colour-index 0·9; slight anisocytosis and hypochromia. She was now having tab. ferrous sulphate gr. 3 thrice daily and anahæmin 2 c.cm. weekly.

It is of course premature to make any definite claims in this case; and now that her condition is satisfactory it is proposed to determine whether exhibition of testosterone alone will maintain the improvement.

We are indebted to Dr. Richard Clarke for permission to record this case, to Dr. F. Lloyd Warren for the assay of 17-ketosteroids, and to The British Drug Houses Ltd. for the implantation tablets.

TRAUMATIC NEURITIS OF THE DEEP PALMAR BRANCH OF THE ULNAR NERVE

SIR,—The interesting article in your issue of June 14 by Dr. Ritchie-Russell and Dr. Whitty, reporting 5 cases of traumatic neuritis of the deep branch of the ulnar nerve, prompts me to add a further case which I saw recently for Mr. Rigby Jones at the fracture clinic of the Connaught Hospital.

A painter and decorator, aged 40, complained of inability to grip firmly with the right thumb and index finger. Nine days previously he had made a long cycling trip in cold weather. On his return home in the evening he found he was unable to straighten the tip of the fifth digit of the right hand; nor could he grip a pen firmly between the thumb

HYPOPITUITARISM AND ANÆMIA

SIR,—Writing in THE LANCET of May 10, Dr. Watkinon, Dr. McMenemey, and Dr. Evans describe 2 cases f hypopituitarism and anæmia, and their treatment with estosterone. This very interesting article has tempted s to record a similar case which appeared to be benefited y testosterone.

A married woman, aged 57, was admitted to hospital under he care of Dr. Richard Clarke, complaining of a feeling of eakness, lethargy, and cold for about a year. She had been ealthy in childhood and early adult life. Her first child was tillborn, but at the age of 34 she gave birth to a child who s still living. Her third pregnancy, at the age of 37, was omplicated by slight antepartum and severe postpartum æmorrhage; the child was stillborn. Thereafter the menstrual periods, previously regular, became irregular, and the menopause came on at the age of 40. She said that she had never been really well since the last stillbirth. During about the past year, in addition to lethargy, which at one time was so severe as to confine her to bed for six weeks, "too weak to move," she had felt the cold bitterly, had attacks of numbness in the fingers, and latterly had some difficulty in walking. There was no recent loss of weight, but she had been very light for some time. Appetite was fair.

The patient's height was 5 ft. 0$^{1}/_{2}$ in. and her weight 7 st. She was slow in movement and in speech, with a dry cracked voice. The skin was fine but dry, the cranial hair thin and scanty, and the nails poorly formed. Axillary and pubic hair were completely absent. The only abnormal pigmentation, on the front of the shins and very patchy, bore indirect testimony to her sensitivity to cold. The tongue was smooth and glazed, and clinically she appeared anæmic. No abnormality was found in the cardiovascular or respiratory systems. The blood-pressure was 100/70 mm. Hg. There was an exaggerated lumbar lordosis and dorsal kyphosis. The gait was slightly spastic; there was increased tone in the left leg; and the left plantar response was extensor. There was some hyperæsthesia of the feet, but no sensory loss or ataxia.

The anæmia proved to be normocytic and hypochromic: red blood-cells 3,200,000 per c.mm.; Hb 7·7 g. per 100 c.cm.; colour-index 0·9; P.C.V. 29 5%; M.C.V. 92 c.μ; M.C.H. 24 γγ: M.C.H.C. 26%; reticulocytes 0·4%. Bilirubin less than 0 2 mg. per 100 c.cm.; plasma sodium 290 mg. per 100 c.cm.; blood cholesterol 135 mg. per 100 c.cm.

X-ray examination of long bones and spine showed diminished calcium content; the sella turcica was within normal limits.

A gruel test-meal showed complete achlorhydria, but free acid appeared after the injection of histamine. The capillary blood-sugar before and at quarter-hourly intervals after ingestion of 50 g. glucose was as follows: before glucose 75 mg. per 100 c.cm.; after glucose 100 mg., 140 mg., 145 mg., and 160 mg. per 100 c.cm. After injection of 10 units of insulin intravenously the blood-sugar fell to 24 mg. per 100 c.cm. in half an hour without symptoms of hypoglycæmia. The 24-hour excretion of 17-ketosteroids was 0·8 mg, and the Kepler test was positive in both procedures.

Sheehan[1] has described many cases of hypopituitarism in women following hæmorrhage at childbirth; some of them had severe anæmia. One of the cases with anæmia complicating hypopituitarism described by Snapper et al.[2] was in a woman who had suffered a postpartum hæmorrhage. The case we have described we believe also to be one of hypopituitarism, due to partial necrosis of the anterior pituitary after postpartum hæmorrhage. Hypopituitarism has in this case, as in those of Snapper, and Watkinson et al.,[3] been associated with anæmia and achlorhydria. Unlike the cases of Snapper, but like those of Watkinson, the blood condition of our patient failed to respond to iron, thyroid, and liver, and her general condition remained stationary and apathetic.

Before the war one of us (G. L. F.) was impressed clinically by the plethora, increase in weight, and raised basal metabolic rate (B.M.R.) occurring, after some weeks, in females treated with testosterone. Reports have since been published of a number of cases of Simmonds syndrome treated with androgens, which produced increase in weight, increase in B.M.R., and nitrogen retention, along with general clinical improvement.[4] [5] [6] [7] In only one of these papers[6] was the blood picture discussed; and in this it was reported as unchanged.

From clinical experience, however, it was decided to try testosterone in our case; and since its addition to the therapy an improvement in the clinical and hæmatological condition has been observed. From the first the patient was given ferri et ammon. cit. gr. 90 daily, 'Anahæmin' 2 c.cm. twice weekly, 'Benerva' 25 mg. daily, and thyroideum siccum. The thyroid, started cautiously with gr. $^{1}/_{4}$ daily, was gradually increased until, 45 days after admission, she was receiving gr. 2 daily. There was, however, very little progress, and on the 27th day six 100 mg. tablets of testosterone were implanted subcutaneously, and before discharge she was transfused with two pints of packed red cells. She was later given methyl testosterone 15 mg. daily, absorbed through the sublabial mucosa, and when seen as an outpatient on the 76th day she had improved clinically and had more energy. Her blood-pressure had risen to 160/100 mm. Hg, but the weight was unchanged.

A month later she was very definite that subjective improvement had occurred. Her blood-pressure was 140/90 mm. Hg, and some pubic hair had appeared. The implanted tablets were still palpable. Red blood-cells 4,000,000 per c.mm., Hb 88%, colour-index 0·9; slight anisocytosis and hypochromia. She was now having tab. ferrous sulphate gr. 3 thrice daily and anahæmin 2 c.cm. weekly.

It is of course premature to make any definite claims in this case; and now that her condition is satisfactory it is proposed to determine whether exhibition of testosterone alone will maintain the improvement.

We are indebted to Dr. Richard Clarke for permission to record this case, to Dr. F. Lloyd Warren for the assay of 17-ketosteroids, and to The British Drug Houses Ltd. for the implantation tablets.

TRAUMATIC NEURITIS OF THE DEEP PALMAR BRANCH OF THE ULNAR NERVE

SIR,—The interesting article in your issue of June 14 by Dr. Ritchie Russell and Dr. Whitty, reporting 5 cases of traumatic neuritis of the deep branch of the ulnar nerve, prompts me to add a further case which I saw recently for Mr. Rigby Jones at the fracture clinic of the Connaught Hospital.

A painter and decorator, aged 40, complained of inability to grip firmly with the right thumb and index finger. Nine days previously he had made a long cycling trip in cold weather. On his return home in the evening he found he was unable to straighten the tip of the fifth digit of the right hand; nor could he grip a pen firmly between the thumb

---

and index finger. On questioning he recalled that at the end of the day's cycling his hand had felt numb along the ulnar border and in the ulnar two digits, but this had passed off in an hour or two. There was no definite history of injury though his journey had taken him over rough roads.

Examination revealed a "mallet" deformity of the fifth digit. There was slight wasting of the adductor pollicis and first dorsal interosseous muscle; there was no voluntary activity in the first dorsal interosseous muscle and the adductor pollicis was weak, but all other intrinsic muscles, as well as the extrinsic muscles, of the hand were acting normally. There was no subjective or objective sensory loss.

This case resembles the first 4 of Dr. Ritchie Russell and Dr. Whitty, wherein the lesion is related to a mild trauma to the ulnar nerve at the wrist or in the palm of the hand; I am unable to agree that this connexion exists in their 5th case.

Such cases are ideally suited for interrupted galvanism. Although the history of the patient reported here was only of nine days' duration, wasting was already visible in the adductor pollicis and first dorsal interosseous muscle. The results of research at Oxford during the war indicate that wasting after denervation of a muscle is minimised by interrupted galvanism. A wasted muscle must mean an inefficient muscle, at least for a time, after its reinnervation.

URTICARIAL REACTIONS TO PENICILLIN

SIR,—Having read Dr. Steingold's article of June 21, and your annotation on the same subject, I wish to report a case of mine.

A girl, aged 11, had a right otitis media for three years following scarlet fever. I gave her a course of five daily injections into the right vastus lateralis muscle of 2 c.cm. oil-wax suspension containing 125,000 units of penicillin per c.cm.

On the eighth day she complained of a painless swollen right thigh, intense itching, and fever. I found a large, hard, red blotch, which covered the whole length of the outer half of the right thigh; there was no tenderness. At the site of the punctures the epidermis was slightly raised and blanched, the condition closely simulating insect-bites. The affected thigh was much thicker than the other. Her temperature was 100°F and she had a furred tongue. Thinking that she was developing an abscess, I put her on sulphathiazole, but on the following day her temperature became normal and the rash was spreading over the whole trunk. I assumed, therefore, that this was an urticarial reaction, and discontinued the sulphathiazole. Four days later, after having spread over the whole trunk, while leaving the other limbs and the face free, the rash completely disappeared without any treatment.

This patient gave no previous history of urticaria or other allergic reactions.

Sheffield.
I. GOTTLIEB.

SIR,—There are several points in Dr. Steingold's article (June 21) which require explanation. Reference was made to intradermal tests using penicillin X, penicillin Y, and pure penicillin. The different penicillins known in Great Britain as I, II, III, and IV are identical with those known as F, G, X, and K in the United States. What therefore is penicillin Y that Dr. Steingold used, and what does he mean by pure penicillin? If by the latter he means the white crystalline penicillin containing over 90% penicillin G, then I think this should be stated.

The article described four patients who when treated with varying doses of penicillin developed urticaria within seven or eight days. Since the reactions were of the delayed type it seems strange that the intradermal tests were positive in ten minutes. The serum of persons with this immediate reaction should contain skin-sensitising antibodies which can be transferred to normal skin. Without carrying out passive transfer tests the conclusions reached from such experiments may lead to faulty reasoning.

The skin tests carried out by Dr. Steingold show results which are at variance with those obtained in this department.

Parliament

ON THE FLOOR OF THE HOUSE

Mr. Bevin has made a statement on the Marshall plan for Europe, which will have to be in fact the European plan for Marshall. And now that Mr. Molotov has joined the consultations the prospects of Europe, East and West, producing a plan of economic rehabilitation may be brighter. Of course this is not a philanthropic UNRRA type of effort by the U.S.A.—it is sound constructive economic building. For unless the nations are sufficiently restored to buy and sell and make and exchange their goods much of the best productive machinery of that republic will rust in idleness.

The Opposition had selected shortages of consumer goods as a subject for debate on Thursday and Sir Stafford Cripps gave the House some interesting information. One of our difficulties is that before the war we had an income of £100–150 million from our overseas investments coming into this country in goods. For these goods we did not need to pay in exports. But now that our investments are largely gone, exports are needed and are drawn from our own stocks of goods. And there is another factor. We have shortages of goods and, on balance, an abundance of purchasing power, for the pre-war low-paid grade of workers are now getting higher wages and their demand is effective—for prams and children's shoes, for example. These facts give us a glimpse of an economic revolution which is proceeding all over the world, and in many countries by methods much more violent than rising prices and changes in the social demand for specific commodities.

The Minister of Health has lately published regulations dealing with terms of pension and superannuation in the National Health Service, and an order setting up the new regional hospital boards. Now that the boards are appointed the interim period before the inception of the National Health Service may be cleared of some of its difficulties and obscurities. The boards will probably advertise their needs for specialists, and when appointments are made the service will begin to assume its working structure. There are many problems ahead, and for those who pictured health centres as well-equipped new buildings with all the latest medical equipment, some disappointment. But it is after all the doctors and nurses who make a good health service; which is just as well, for new buildings on any large scale will have to come later.

MEDICUS, M.P.

FROM THE PRESS GALLERY

Venereal Disease in the Army

In the House of Commons on June 25 Dr. S. SEGAL raised the question of the incidence of venereal disease among our overseas forces. The statistics given elsewhere were, he believed, subject to certain fallacies, for they dealt with the incidence of venereal disease over twelve months per 1000 men in a given command, but they failed, he suggested, to take into account that these 1000 men over a period of twelve months were in a mobile state, with changes taking place through posting and replacement. Hence over a period of twelve months the numbers were probably considerably greater. Though the incidence of venereal disease was grave, the real problem today was how far risks of exposure to disease had been taken for every given case of disease which had been recorded. Considering the well-known methods of prophylaxis and early treatment, the high percentage of cures, and low proportion of relapses, Dr. Segal thought that, even if the figures had been less serious, they would still occasion grave disquiet. They were symptomatic of the loosening of moral ties that had followed every major war.

In so far as this problem affected our troops stationed at home Dr. Segal held that it was not primarily the concern of the War Office. It was firstly the concern of the Church, upon whom lay the responsibility of preaching incessantly the ideals of self-discipline and self-restraint, of a high standard of moral values, and of the sanctity of family life. A heavy responsibility also rested upon the State in making higher standards of education available to as large a proportion of the opulation as possible; in providing houses for newly arried couples: and in establishing a system of family lowances whereby the amount would increase with ich successive child. But for our troops stationed verseas the responsibility belonged primarily to the ar Office. Why was the incidence of venereal disease the Far East six times as high, and in Germany and ustria today almost five times as high as in the Middle ast? Dr. Segal felt that it should be the aim of the ar Office to encourage the recruit to retain as far as ossible his civilian outlook during the brief term of his ilitary service.

Mr. **JOHN FREEMAN**, under-secretary of State for War, greed that this difficulty would only be overcome by eating conditions in the Services overseas which would revent the temptation which led to this scourge. lthough he did not underestimate the seriousness of e problem, there was ground for the belief that the peak ad now been passed. For the first quarter of 1946 the hine Army figures were 30·4 per 1000; for the second quarter 41·8; for the third quarter 44·6; for the fourth quarter 1·8; and for the first quarter of this year 30. The build-up the middle of last year, and the reduction at the nd of last year and the beginning of this year were eflected substantially in the commands. It was worth ointing out also that while these were terrible figures ey were lower than those for a similar period after the rst world war, and it must be remembered that men re far more ready to report this disease than they re in the past.

He could not give a clear answer to Dr. Segal's question y the incidence of the disease in the Middle East ould be lower than in the Far East and north-western urope, but the conditions under which men lived in e Services in the Middle East were not conducive to enereal disease. In Germany and Austria they were nducive to the disease, and in both areas the incidence the disease among the civilian population was high. the Far East it had been difficult to control the sources infection, and only recently had they started to make rogress on that side of the problem. He could assure e House that the War Office fully recognised the nportance of trying to give the Serviceman the opportunity of making civilian contacts, and there were more ivilians doing welfare work overseas than during the ar. While it was possible to take medical measures limit the seriousness of this problem where it had tarted, clearly the way to eliminate it was by a moral, ducational, and welfare approach.

QUESTION TIME

Interim Report on Negotiations

Dr. S. **SEGAL** asked the Minister of Health whether any interim eport would be issued to the House on the progress of egotiations with the negotiating committee of the medical rofession; and when the interim report could be expected. —Mr. A. **BEVAN** replied: I anticipate that these negotiations ill remain confidential until the outcome is known. Dr. **EGAL**: Can the Minister give an assurance to the House hat, if at some future date an interim report is received it ill be just circulated to hon. Members of the House rather han issued for private circulation among the 55,000 medically ualified members of the profession?—Mr. **BEVAN**: These re negotiations with the profession about the conditions on hich they propose to serve in a national service. They o not directly concern hon. Members of the House, except in heir medical capacities. For instance, if there were negotiations going on between the Government and members of the ivil Service on conditions of employment the decision ould not be first announced to the House of Commons. his is essentially a matter for the medical profession in the irst instance, and afterwards for the House, if it wishes.

Administrative Machinery

Mr. S. **HASTINGS** asked the Minister whether, in selecting epresentatives of the medical profession for the local executive ouncils under the new Health Act, he was asking for nominations from the medical committees in the various areas: and whether he was aware that in not a few of these areas medical committees were elected in 1938 and there had been no election since.—Mr. **BEVAN** replied: Appointments of medical members to executive councils are made by the local medical committees and not by the Minister. I am aware that in most areas there have not been elections for panel committees since 1939, and therefore my recognition of local medical committees for the new service has been provisional.

Dr. **SEGAL** asked the Minister how, and by whom, the chairman of a local health service executive council was selected; which local bodies were consulted; and what qualifications were required in assessing suitability for this post.—Mr. **BEVAN** replied: Chairmen of executive councils are appointed under the National Health Service Act by the Minister of Health. I am making careful inquiries in each case, but there have been no formal consultations. No particular qualifications can be specified: my object is to get good chairmen. Dr. **SEGAL**: Is the Minister aware that in at least one area public opinion has been outraged by the appointment of a chairman who has had a pecuniary interest in hospital contracts in the past? Is it already too late to reconsider this appointment?—Mr. **BEVAN**: I do not know the instance which the hon. Member has in mind, but in these appointments I am not concerned with party or political considerations, but to get the right kind of chairman for the bodies who have to do this work. If there is any instance of nepotism, or near nepotism, I would like the hon. Member to bring it to my notice.

Local Health Committees

In answer to a question, Mr. **BEVAN** stated that all local health authorities except Norfolk and Cardigan county councils had constituted health committees, and Norfolk county council had appointed a health services reorganisation committee which was engaged on the preparation of proposals.

Land for Health Centres

Mr. **HASTINGS** asked the Minister to what extent major local authorities were, at the present time, able to acquire land to enable them to build health centres when conditions were more favourable; and whether he would take steps to increase these powers where they were insufficient.—Mr. **BEVAN** replied: There are ample powers in section 58 of the National Health Service Act, but I am advised that these cannot be exercised yet. Provincial authorities can proceed under the Public Health Act, 1936. The powers conferred by the corresponding London Act are narrower, but I fear that I cannot promise legislation to increase them. Mr. **HASTINGS**: Does the Minister realise how important it is that sites that are required for health centres should not be lost for all time, because sufficient powers are not available?—Mr. **BEVAN**: I doubt whether sites are being lost. At all events, it is no use at the moment acquiring them too far ahead of time, because the health centres could not be built at the present time for lack of building materials and labour owing to the prior claims of housing. Next year the position may be different.

Hospital Equipment and Supplies

Mr. H. **DAVIES** asked the Minister to what extent it was proposed to obtain equipment and supplies for hospitals under the National Health Service by centralised purchase, in place of the present system of purchase by individual hospitals; and whether a similar policy would be applied to installation and maintenance services.—Mr. **BEVAN** replied: Hospital equipment and supplies cover a wide range. For some items, there may be advantage in central purchase. But where present methods of supply and servicing are working satisfactorily it is not proposed, at the outset of the new service, to interfere with them. For the time being central purchase will be limited to major equipment which is in short supply, and various other items which may be found to lend themselves to central purchase on grounds of economy or better efficiency.

Tuberculosis in the Air Force

Mr. H. **USBORNE** asked the Secretary of State for Air how many men had been discharged from the R.A.F. suffering from tuberculosis, between September, 1939, and June, 1945, and June, 1945, and the present time, respectively.—Mr. P. **NOEL-BAKER** replied: The numbers are as follows: September, 1939–June, 1945 = 6642; July, 1945–June, 1947 = 3147. The increase in the number of discharges per annum during the later period is largely due to the wider application of radiography to the Royal Air Force. An X-ray examination is now provided for new entrants and for members of the Service on release from overseas.

and index finger. On questioning he recalled that at the end of the day's cycling his hand had felt numb along the ulnar border and in the ulnar two digits, but this had passed off in an hour or two. There was no definite history of injury though his journey had taken him over rough roads.

Examination revealed a "mallet" deformity of the fifth digit. There was slight wasting of the adductor pollicis and first dorsal interosseous muscle; there was no voluntary activity in the first dorsal interosseous muscle and the adductor pollicis was weak, but all other intrinsic muscles, as well as the extrinsic muscles, of the hand were acting normally. There was no subjective or objective sensory loss.

This case resembles the first 4 of Dr. Ritchie Russell and Dr. Whitty, wherein the lesion is related to a mild trauma to the ulnar nerve at the wrist or in the palm of the hand; I am unable to agree that this connexion exists in their 5th case.

Such cases are ideally suited for interrupted galvanism. Although the history of the patient reported here was only of nine days' duration, wasting was already visible in the adductor pollicis and first dorsal interosseous muscle. The results of research at Oxford during the war indicate that wasting after denervation of a muscle is minimised by interrupted galvanism. QUESTION TIME

Interim Report on Negotiations

Dr. S. Segal asked the Minister of Health whether any interim eport would be issued to the House on the progress of egotiations with the negotiating committee of the medical rofession; and when the interim report could be expected. —Mr. A. Bevan replied: I anticipate that these negotiations will remain confidential until the outcome is known. Dr. Segal: Can the Minister give an assurance to the House that, if at some future date an interim report is received it will be just circulated to hon. Members of the House rather han issued for private circulation among the 55,000 medically qualified members of the profession?—Mr. Bevan: These are negotiations with the profession about the conditions on which they propose to serve in a national service. They do not directly concern hon. Members of the House, except in their medical capacities. For instance, if there were negotiations going on between the Government and members of the Civil Service on conditions of employment the decision would not be first announced to the House of Commons. This is essentially a matter for the medical profession in the first instance, and afterwards for the House, if it wishes.

Administrative Machinery

Mr. S. Hastings asked the Minister whether, in selecting representatives of the medical profession for the local executive councils under the new Health Act, he was asking for nominations from the medical committees in the various areas: and whether he was aware that in not a few of these areas medical committees were elected in 1938 and there had been no election since.—Mr. Bevan replied: Appointments of medical members to executive councils are made by the local medical committees and not by the Minister. I am aware that in most areas there have not been elections for panel committees since 1939, and therefore my recognition of local medical committees for the new service has been provisional.

Dr. Segal asked the Minister how, and by whom, the chairman of a local health service executive council was selected; which local bodies were consulted; and what qualifications were required in assessing suitability for this post.—Mr. Bevan replied: Chairmen of executive councils are appointed under the National Health Service Act by the Minister of Health. I am making careful inquiries in each case, but there have been no formal consultations. No particular qualifications can be specified: my object is to get good chairmen. Dr. Segal: Is the Minister aware that in at least one area public opinion has been outraged by the appointment of a chairman who has had a pecuniary interest in hospital contracts in the past? Is it already too late to reconsider this appointment?—Mr. Bevan: I do not know the instance which the hon. Member has in mind, but in these appointments I am not concerned with party or political considerations, but to get the right kind of chairman for the bodies who have to do this work. If there is any instance of nepotism, or near nepotism, I would like the hon. Member to bring it to my notice.

Local Health Committees

In answer to a question, Mr. Bevan stated that all local health authorities except Norfolk and Cardigan county councils had constituted health committees, and Norfolk county council had appointed a health services reorganisation committee which was engaged on the preparation of proposals.

Land for Health Centres

Mr. Hastings asked the Minister to what extent major local authorities were, at the present time, able to acquire land to enable them to build health centres when conditions were more favourable; and whether he would take steps to increase these powers where they were insufficient.—Mr. Bevan replied: There are ample powers in section 58 of the National Health Service Act, but I am advised that these cannot be exercised yet. Provincial authorities can proceed under the Public Health Act, 1936. The powers conferred by the corresponding London Act are narrower, but I fear that I cannot promise legislation to increase them. Mr. Hastings: Does the Minister realise how important it is that sites that are required for health centres should not be lost for all time, because sufficient powers are not available? —Mr. Bevan: I doubt whether sites are being lost. At all events, it is no use at the moment acquiring them too far ahead of time, because the health centres could not be built at the present time for lack of building materials and labour owing to the prior claims of housing. Next year the position may be different.

Hospital Equipment and Supplies

Mr. H. Davies asked the Minister to what extent it was proposed to obtain equipment and supplies for hospitals under the National Health Service by *centralised* purchase, in place of the present system of purchase by individual hospitals; and whether a similar policy would be applied to installation and maintenance services.—Mr. Bevan replied: Hospital equipment and supplies cover a wide range. For some items, there may be advantage in central purchase. But where present methods of supply and servicing are working satisfactorily it is not proposed, at the outset of the new service, to interfere with them. For the time being central purchase will be limited to major equipment which is in short supply, and various other items which may be found to lend themselves to central purchase on grounds of economy or better efficiency.

Tuberculosis in the Air Force

Mr. H. Usborne asked the Secretary of State for Air how many men had been discharged from the R.A.F. suffering from tuberculosis, between September, 1939, and June, 1945, and June, 1945, and the present time, respectively.—Mr. P. Noel-Baker replied: The numbers are as follows: September, 1939–June, 1945 = 6642; July, 1945–June, 1947 = 3147. The increase in the number of discharges per annum during the later period is largely due to the wider application of radiography to the Royal Air Force. An X-ray examination is now provided for new entrants and for members of the Service on release from overseas.

Obituary

REGINALD CECIL BLIGH WALL

M.A., D.M. OXFD, F.R.C.P.

Dr. Cecil Wall came of a medical family on the spear and distaff side. His father and his grandfather both practised in Bayswater, and his father Dr. R. B. Wall was master of the Society of Apothecaries in 1909–10. His mother was the daughter of James Luke, F.R.S., who was president of the Royal College of Surgeons in 1862.

Cecil Wall was educated at Bradfield College, of which he later became a trustee and councillor, and at the Queen's College, Oxford, which he entered with a Fitzgerald exhibition. At Oxford he proved himself a crack rifle shot, winning the Spencer cup in 1888 and the Rifle Association's bronze medal in 1891. After taking his B.A. in 1893 he went to the London Hospital with a scholarship, and he qualified in 1897, taking his degree the following year. In 1899 he was awarded the Andrew Clark scholarship in medicine and pathology. Having held house-appointments at the London he joined the staff of the Eastern Dispensary and the Poplar Hospital, and later he was appointed to the staffs of his own hospital and of the Brompton. He was also physician to the Alliance Insurance Company.

Swaine

At the London Hospital Dr. Wall became known to generations of students as an able teacher who gave much thought to their instruction. He had a good education and a good brain, and his teaching of accurate observation and deduction was the means by which many learnt a scientific approach at the bedside. On ward rounds his habit was to demonstrate the first case in detail, devoting perhaps half an hour to its demonstration and discussion. By careful choice of cases he arranged that his students should see him handling comprehensively examples of all the commoner conditions, and consciously or unconsciously they gained much profit. He also made it a practice to spend a long afternoon each week in visiting all his patients unaccompanied; and it was largely this conscientious approach to hospital work that made his reputation as a physician and preserved that reputation over long years in which medicine underwent radical changes. By the people of the East End district which the London Hospital chiefly serves, his merits were fully appreciated.

Though particularly well known for his expertness in diseases of the chest, he by no means confined himself to them. Chorea was the subject of his valuable Bradshaw lecture of 1920, delivered before the Royal College of Physicians, to whose fellowship he had been elected in 1908. Like his Schorstein lecture, given at the London Hospital in 1928, it appeared in our columns. At the London he was a lecturer in therapeutics as well as in diseases of the chest. His interest in teaching was also shown during his tenure of the post of dean of the Brompton Hospital medical school, and as a member of the boards of the medical faculties of Oxford and London, and a member of the board of advanced medical studies of London University. He had a considerable gift of organisation and was a capable chairman at professional meetings. As an examiner he served the universities of Oxford and London, the Royal College of Physicians, and the Society of Apothecaries.

A man of deep loyalties, giving affectionate service to his old school and university and to his two hospitals, Dr. Wall had a special place in his heart for the Apothecaries. In the 300 years of its existence the society can, indeed, have had no more devoted member, nor one who believed more sincerely in its importance to the nation and to medicine. Admitted to the yeomanry in 1891, he was master in 1932–33, and from 1934 to 1939 was its representative on the General Medical Council. From 1934 until his death he held the of archivist to the society, and was the better enabled to make full use of his antiquarian talents. In 19 he gave the Thomas Vicary lecture at the Royal Coll of Surgeons on the History of the Surgeons' Company 1745–1800, which he expanded and published two y later as an entertaining monograph to which Sir D' Power contributed a foreword. In 1944 he continued story in his FitzPatrick lectures to the Royal College Physicians which dealt with the history of the En medical profession in the 18th and 19th centuries. wide knowledge of medicine and its history covered details of pharmacy both ancient and modern: he could point out, for example, that in the first edition of the *British Pharmacopœia* the dose of calomel had been 15 grains and that there had not been any edition in which the dose was not reduced to a lesser one. As archivist at Apothecaries' Hall he knew the story of every picture, every bit of furniture, and every piece of silver that the society possessed, as well as of every piece of the society's property and in which parts of it what had stood before from the days of the Tudors. He was prepared to speak on any or on all of these subjects at any length and at any moment, and he always spoke with interest, though this was somewhat marred by a monotony of the voice in later years owing to his deafness.

His little history of the society and its hall (19 traced the lineal descent of the general medical practitioner of today from the apothecary of the 17th century; and for some fifteen years he had been working on a larger history which remains for other hands to complete.

Dr. Wall married Dorothy, daughter of H. Innes Fripp, and they had a son and two daughters. He died at his home in London on June 19, aged 77.

LEONARD FINDLAY

"Professor Findlay was a master of the art of discourse," writes a colleague, "and I shall never forget the tall, firm, erect, figure striding into the ward ready at every opportunity to subject each statement and each observation to the most critical scrutiny; but his criticisms were so astute and so honest that they never caused offence to an honest observer. One always knew that he was prepared to have his statements torn to pieces and subjected to the same treatment as those of others. The care he would take in delving to the limits of each problem was always an object lesson; and, like all true clinicians and scientists, he always noted down his own observations and made his assistants do likewise. There can have been few men better able to set the young doctor on the difficult path of a scientific approach to clinical medicine. He taught one to evaluate each laboratory finding, each clinical sign, each symptom, and so the whole child."

Births, Marriages, and Deaths

BIRTHS

ANDERSON.—On June 23, at East Sheen, the wife of Dr. I. M Anderson—a daughter.

BRYCE-CURTIS.—On June 23 in London, the wife of Dr. P. J Bryce-Curtis—twin daughters.

CHILDS.—On June 19, at Southsea, the wife of Dr. H. K. Childs—a daughter.

EAGER.—On June 21, at Oxford, the wife of Dr. R. G. Eager—a daughter.

GRIFFITHS.—On June 22, at Oxford, the wife of Dr. R. C. L. Griffiths—a daughter.

HUNT.—On June 22, at Brighton, the wife of Dr. G. N. Hunt—a son.

NASH.—On June 26, in London, the wife of Dr. F. W. Nash—a son.

SIMON.—On June 27, the wife of Dr. George Simon—a daughter

MARRIAGES

GIBSON—WELLS.—On June 24, in London, M. O. J. Gibson, M.B. to Sarah Josephine Wells.

DEATHS

ARMSTRONG.—On June 23, in Liverpool, Hubert Armstrong, M.D. Vict.

HARMER.—On June 25, at George, S. Africa, John Daniel Harmer, O.B.E., M.B. Edin., F.R.C.S.E.

JONES.—On June 24, at Ringwood, Hants, Henry Travers Jones, M.B. Lond., D.P.M., aged 66.

KERBY.—On June 25, Theo Rosser Fred Kerby, M.R.C.S., D.M.R.E.

PACKER.—On June 26, Harry Dixon Packer, C.I.E., M.R.C.S., colonel R.A.M.C. (retired), aged 75.

SEARLE.—On June 23, in Kenya, Charles Frederick Searle, M.C. T.D., M.D. Camb., D.P.H.

SHAW.—On June 26, in London, John Arthur Pilkington Shaw, M.R.C.S.

Notes and News

THREE-DIMENSIONAL PHOTOGRAPHY

STEREOSCOPIC effect has been achieved in photography, a device invented in France, without special viewing aratus. For instantaneous exposures a multiple camera objectives in line along a fixed base is used, while another e of camera moves during exposure over an arc of 16°. inary photographic material is used, but the photograph ounted behind a grid of thin glass treated with cellulose tate comprising a lenticular optical system. The results remarkable, and as the process is not expensive it should, the owners claim, have a future in medical teaching. It l be interesting to see if it can be successfully applied to iography, particularly of the head and chest. The process eing developed in Britain by Deep Pictures Ltd., 150, New nd Street, London, W.1.

MEDICAL BOOKS AT OXFORD

To show academic hospitality to the Association of Surgeons d the International Congress of Physiologists who meet Oxford this month, an exhibition has been arranged in e Bodleian Library illustrating the history of medicine, rgery, and physiology from classical times to the present y. The manuscripts include works written by Greek, tin, and Arabic writers beginning with Hippocrates. One the medieval manuscripts exhibited is a medical treatise, itten about 1290, containing the earliest known representa n of a human dissection. The printed books date from 74 and include early editions of Vesalius, Geminus, Paré, nacre, William Harvey, Thomas Willis, and Thomas Sydenam. The exhibition is in two sections; one general, the other voted to The Oxford Scene. In the latter are shown some rious quack advertisements circulated in Oxford nearly 0 years ago. Other manuscripts show that as early as 1594 e faculty of medicine was concerned with the smoking of bacco, while *Artificiall Embellishments*, published in 1665 y an Oxford doctor, is a comprehensive guide to beauty lture. The exhibition is open free to the public daily 2 P.M. to 5 P.M.) except Saturdays and Sundays. An illustrated catalogue is on sale (price 1s.).

SOURCE OF ANTILEPROTIC OILS

Of the innumerable genera of the flacourtiaceæ, three roduce oil used in leprosy—hydrocarpus, oncoba, and arpotroche. In *As Flacourtiáceas Antilepróticas*, a compre ensive work of 132 pages produced in the leprosy prophylaxis epartment at Sao Paulo, Brazil, Helena Possolo describes he botanical features of the genera and species concerned nd the physical and chemical qualities of the oils extracted rom the seeds. The introduction deals with the geographical istribution of the plants and the history of their use, and he illustrations give details of the more important species. There is also a bibliography of over 300 references.

University of Oxford

On July 25 the honorary degree of D.SC. will be conferred on Dr. S. A. S. Krogh of the Zoophysiological Laboratory, Copenhagen, Dr. A. Szent-Györgyi of the University of Budapest, Dr. H. S. Gasser, director of the Rockefeller Institute for Medical Research, New York, and Prof. C. H. Best, F.R.S., head of the Banting-Best Institute of Medical Research, Toronto.

University of Birmingham

Mr. P. B. Medawar, a fellow of Magdalen College and a member of the department of zoology and comparative anatomy of the University of Oxford, has been appointed Mason professor of zoology in the university. His research at Oxford has included studies of nerve suture published in these columns and elsewhere.

Royal College of Surgeons of England

Dr. W. K. Livingston, professor of surgery of the University of Oregon, will deliver a Moynihan lecture at the college, Lincoln's Inn Fields, W.C.2, on Tuesday, July 8, at 6.15 P.M., on the Physiological Responses to Wounding.

London Hospital

Sir Frederick Ogilvie will present the prizes in the college library on Wednesday, July 9, at 3 P.M.

University of St. Andrews

At recent examinations the following were successful:

M.D.—D. C. Sinclair (with honours); H. H. A. Elder.

M.B., Ch.B.—J. D. Andrew, Margaret M. Downes, D. M. Green, Margaret Lamb, J. M. McGilchrist, E. C. Mathieson, Jessie Muirhead, R. J. A. Nicol, J. J. A. Reid, Margaret W. Richardson, W. B. Robertson, C. E. G. Smith, G. R. Tudhope (with commendation); Mary Auld, Mona A. Barron, Christine Benson, W. S. Bowman, Ruth Brogden, J. F. Butchart, G. S. Caithness, Diana Campion, Gillian Crow, A. L. M. Davidson, Margaret B. Dempster, K. P. Duncan, Alexander Ewing, A. D. Forrest, J. P. Fraser, J. A. Freeman, J. L. Hamilton, A. P. B. Harston, Margaret J. Jackson, Olive M. Landsman, A. G. R. Law, J. S. M. Low, Sheila McCall, R. H. A. MacGranthin, Donald McLauchlan, Margaret C. MacLeod, R. K. Machell, A. B. Mann, Helen S. Mathewson, D. R. S. Ritch, I. K. Sharp, Ada H. Shepherd, William Shepherd, Isobel M. Soutar, O. H. Taylor, A. C. Traill, Elizabeth White, Nora P. Woods.

University of London

Sir Francis Fraser, director of the British Postgraduate Medical Federation, has been appointed deputy vice-chancellor of the university for 1947–48. Dr. K. J. Franklin, has been appointed to the university chair of physiology at St. Bartholomew's Hospital, and Miss Margaret Murray, D.SC. to the university chair of physiology at Bedford College.

Dr. Franklin, who is 49, was educated at Christ's Hospital, and Hertford College, Oxford, where he was a classical scholar. During the 1914–18 war he served with the Royal Field Artillery in France and Belgium. After taking first-class honours in animal physiology in 1921, he held demonstratorships in physiology at Oxford and at St. Bartholomew's Hospital, whence he took his medical degree in 1924 and his D.M. three years later. In 1924 he was elected a fellow of Oriel College, where he now holds the posts of tutor, librarian, and lecturer in physiology. In 1924 he also became university demonstrator of pharmacology, an appointment which he held till 1938. In 1925 he was awarded a Radcliffe travelling fellowship and he spent the next year as assistant professor of physiology at the University of Michigan. In 1935 Dr. Franklin was appointed assistant director of the Nuffield Institute for Medical Research, and he is also dean of the Oxford medical school. He has published a *Short History of Physiology* (1933) and a *Monograph on Veins* (1937) and he has edited translations of Richard Lower's *De Corde* (1669), of *De Venarum Ostiolis* (1603), and of *Hieronymus Fabricius of Aquapendente*. He is a member of the Oxford teams whose investigations on circulation of the blood in the fœtus and in the kidney have lately been published. In 1940 he was elected F.R.C.P.

Commonwealth and Empire Health and Tuberculosis *Conference*

A few tickets for this conference, which is to be held in the Central Hall, Westminster, on July 8, 9, and 10, are still available, and may be had from Dr. Harley Williams, N.A.P.T., Tavistock House North, Tavistock Square, W.C.1.

Tuberculosis Educational Institute

The institute is holding a refresher course at the Dunn School of Pathology, Oxford, from Sept. 23 to 26, on the pathology and bacteriology of tuberculosis. The speakers will include Sir Howard Florey, F.R.S., Prof. J. W. S. Blacklock, Mr. E. Chain, D. PHIL., Dr. Robert Cruickshank, Miss Honor Fell, D.SC., Dr. K. F. W. Hinson, Dr. Jethro Gough, Dr. A. Q. Wells, Prof. W. H. Tytler, Dr. D. Barron Cruickshank, Dr. E. Nassau, Dr. C. E. Dukes, Dr. S. R. Gloyne, and Dr. Hyme Lempert. Further information may be had from Dr. Harley Williams, Tavistock House North, Tavistock Square, London, W.C.1.

Royal Society of Medicine

On July 1, at the annual meeting, Sir Maurice Cassidy, the president, presented the society's gold medal to Sir Alexander Fleming, F.R.S., and to Sir Howard Florey, F.R.S., who was unavoidably absent. The recipient of the Hickman medal, Prof. R. R. Macintosh, was introduced by Dr. Stanley Rowbotham, who described the award of this medal as the highest honour that an anæsthetist can be paid by his colleagues. The president also handed the diplomas of honorary fellowship to Prof. Naguib Mahfouz Pasha, Sir Edward Mellanby, F.R.S., and Dr. C. M. Wenyon, F.R.S., and to the Swedish chargé d'affaires as representative of Prof. Einar Key.

The following are the officers for the coming year:

President: Sir Maurice Cassidy. Hon. treasurers: Dr. Charles Newman and Mr. L. R. Broster. Hon. secretaries: Mr. W. A. Pool and Dr. A. T. M. Wilson. Hon. librarians: Mr. E. K. Martin and Dr. Thomas Hunt. Hon. editors: Mr. Eric Crook and Dr. E. R. Cullinan. Other members of council: Miss Geraldine Barry, Dr. E. R. Boland, Sir Ernest Rock Carling, Dr. E. A. Cockayne, Mr. Zachary Cope, Dr. Macdonald Critchley, Dr. Maurice Davidson, Dr. D. T. Davies, Mr. Charles Donald, Dr. Charles Harris, Mr. J. B. Hunter, Dr. H. L. Marriott, Mr. M. F. Nicholls, Mr. R. H. O. B. Robinson, Dr. A. C. Roxburgh, and Sir Henry Tidy.

The annual report shows that there are now 8715 fellows and members of the society.

Medical Art Society

This society is to hold an exhibition at 1, Wimpole Street, London, W.1, from July 17 to 26. The secretary is Dr. Henry Wilson, 142, Harley Street, W.1.

Unesco Awards

UNESCO has awarded grants-in-aid to 47 scientists in 10 European countries and in the U.S.A., for the purpose of attending the sixth International Congress for Experimental Cytology, which is to be held in Stockholm from July 10 to 17.

L.C.C. and N.H.S. Act

The health committee's proposals for carrying out the London County Council's duties under section 26 (vaccination and immunisation) and section 27 (ambulance services) of the National Health Service Act were considered by the council last Tuesday.

Diabetic Association

At 10 A.M. on Friday, July 18, Prof. Charles Best, F.R.S., will deliver the first Banting lecture at King's College Hospital, London, S.E.5. In the afternoon and on the morning of Saturday, the 19th, there will be further lectures and demonstrations in the diabetic and biochemical departments. Doctors and medical students are invited to attend.

Medical Treatment for Civilian Repatriates

Till now civilians repatriated from enemy-occupied territories have been entitled to six months' free medical treatment irrespective of whether their illness was due to their internment or not. These arrangements have now been cancelled (Ministry of Health circular 111/47), but patients whose illness is attributable to their internment will continue to be an E.M.S. responsibility.

Epsom College

Dr. Harold Spitta has been appointed chairman of the council in succession to the late Mr. D. C. Bartley. During the past year the following governors have been elected to fill vacancies on the council: Surgeon Vice-Admiral Sir Basil Hall, Brigadier H. Glyn Hughes, Mr. R. W. Raven, Lieut.-Colonel Sir Bernard Reilly, Dr. Eric Sargent, and Mr. Noel Waterfield. In the report presented at the annual meeting on July 4 it was announced that during the period 1945–47 eleven open scholarships and exhibitions to Oxford and Cambridge had been won. "Successes in the London 1st M.B.," the report continues, "have shown an abrupt decline, not easily to be explained by a falling off in the quality of candidates, since successes in the equivalent examinations at Oxford and Cambridge have remained as high as ever."

Appointments

BRUN, CLAUDE, M.B. Lond., F.R.C.S.: accident officer, Salford Health Committee and Salford Royal Hospital joint accident service.

HOLDEN, HERBERT, M.B. Lpool: asst. radiotherapist, General Hospital, Northampton.

RASSIN, MEYER, M.B. Edin., F.R.C.S.E.: surgeon, West Middlesex County Hospital.

ROBSON, T. W., M.B. Edin., D.P.H.: *deputy M.O.H. and senior asst.* school M.O., Reading.

STENGEL, ERWIN, M.D. Vienna: director of clinical research, Graylingwell Hospital, Chichester.

WATKINS-PITCHFORD, JOHN, M.B. Lond., D.P.H.: H.M. inspector of *factories*.

WILSON, ELIZABETH, M.B. Glasg.: asst. M.O.H. and asst. school M.O., Wigan.

Guy's Hospital, London:

MOYNAHAN, E. J., M.R.C.P.: registrar, dermatological department.
SALMON, L. F. W., M.B.E., M.B. Lond.: specialist in ear, nose, and throat department.
YOUNG, A., F.R.C.S.: specialist in ear, nose, and throat department.

St. Mary's Hospital Medical School (*University of London*):

SAMES, C. P., M.S. Lond., F.R.C.S.: asst. director of the surgical unit.
STANLEY, B. E. C., M.B. Lond., F.R.C.S.: asst. in the surgical unit.

North Middlesex County Hospital:

FAUX, NANCIE, M.B. Lond., D.A., D.P.H.: senior anæsthetist.
KNOWLES, G. S. A., M.B. Lond., D.A.: senior anæsthetist.
REID, G., M.B. Edin., F.R.C.S.E.: temporary surgeon.

City General Hospital, Leicester:

HIRSCH, W. P., M.R.C.S., M.R.C.O.G.: obstetrical and gynæcological registrar.
SHIELD, J. B., M.B. Edin., F.R.C.S.E.: chief asst., orthopædic department.

Royal Sanitary Institute

On Saturday, July 12, a meeting of the institute is to be at 10.30 A.M. in the Guildhall, Worcester. Mrs. E. Moore will speak on a Home Help and Domestic Help Se and Mr. T. W. Marsden on Public-health Aspects of Relief.

Return to Practice

The Central Medical War Committee announces Dr. James S. Young, M.R.C.O.G., has resumed civilian pra at 57, Harley Street, London, W.1 (Langham 3556).

Diary of the Week

JULY 6 TO 12

Monday, 7th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
3.45 P.M. Prof. C. M. West: Anatomy of Circulatory Sy (First lecture.)
5 P.M. Prof. R. A. Gregory: Stomach.
WESTMINSTER HOSPITAL SCHOOL OF MEDICINE, Horseferry R S.W.1
5 P.M. (Meyerstein lecture theatre.) Clinico-pathological de stration of two cases of aplastic anæmia.

Tuesday, 8th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Professor West: Anatomy of Circulatory Sy (*Second lecture.*)
5 P.M. Prof. G. W. Pickering: Nutrition of Heart.
6.15 P.M. Prof. W. K. Livingston: Physiological Respons Wounding. (Moynihan lecture.)
COMMONWEALTH AND EMPIRE HEALTH AND TUBERCU CONFERENCE
10 A.M. (Central Hall, Westminster, S.W.1.) Dr. G. J. Whe Dr. F. J. Wiles, Dr. Claude Taylor, Dr. P. V. Benjar Tuberculosis in the Commonwealth, including I Diseases.
2.15 P.M. Mr. Aneurin Bevan, M.P., Dr. Norman Tatte Dr. B. R. Clarke: National Health Service Act (I —and its effect on tuberculosis work.
INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray's Inn R W.C.1
5 P.M. Mr. V. E. Negus: Nose, Nasopharynx, and Paran Sinuses.

Wednesday, 9th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. D. V. Davies: Joints.
5 P.M. Prof. Alan Kekwick: Nutrition and the Surgeon (Prote
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION
11 A.M. (Winter Garden, Eastbourne.) Annual meeting.
2.30 P.M. Dr. W. G. Masefield: Presidential address.
COMMONWEALTH AND EMPIRE HEALTH AND TUBERCU CONFERENCE
10 A.M. Dr. G. S. Todd, Mr. Alexander Gray, F.R.I.B.A., Jane Drew, F.R.I.B.A., Dr. Robert Cunningham: S torium Design at Home and Abroad.
11.30 A.M. Dr. R. R. Trail, Dr. Etienne Berthet: Care Rehabilitation Schemes.
2.15 P.M. Prof. W. H. Tytler, Dr. E. R. Long, Dr. A. Q. W Dr. H. C. Hinshaw, Dr. K. N. Irvine, Dr. H. S. Wi Specific Measures in Prevention and Treatment of Tu culosis, Streptomycin, B.C.G., &c.
MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH
8.30 P.M. (7, Drumsheugh Gardens, Edinburgh.) Prof. J. Learmonth, Miss Catherine Burt, Dr. Douglas Matthe Anticoagulants.

Thursday, 10th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. H. A. Harris: Limb Plexuses. (First lecture.)
5 P.M. Professor Kekwick: Nutrition and the Surgeon (Wa and Salts).
6.15 P.M. Prof. H. Jackson: Rôle of Anatomy in Symptomatol of Lumbar Disk Protrusions. (Hunterian lecture.)
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION
10.15 A.M. (Eastbourne.) Dr. Geoffrey Evans, Dr. Noel Har Place of Psychiatry in Medicine.
2.15 P.M. Dr. Donald Stewart: Relation of Society to Occu tional Health. Dr. J. Thwaites: Psychiatry in Relat to General Practice.
ABERNETHIAN SOCIETY, St. Bartholomew's Hospital, E.C.1
5.15 P.M. Prof. John Fulton: Harvey Cushing and His Book
COMMONWEALTH AND EMPIRE HEALTH AND TUBERCULO CONFERENCE
10 A.M. Dr. F. R. G. Heaf, Dr. N. L. Rusby, Dr. D. R. W. Cowa Human Factor—Propaganda, Psychology, Education.
2.15 P.M. Mr. A. Creech Jones, M.P., Dr. C. E. Bevan, Dr. J. G. Turner, Dr. W. S. Gilmore, Dr. Edgar Cochrane, Dr. R. Snodgrass, Dr. W. J. Vickers: Colonial Tubercul Services.

Friday, 11th

3.45 P.M. Professor Harris: Limb Plexuses. (Second lecture.)
5 P.M. Dr. N. F. Maclagan: Liver Efficiency Tests. (First lectu
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION
10.15 A.M. (Eastbourne.) Mr. F. C. Webster, F.R.I.B.A., J. J. O'Reilly: Planning of Modern Psychiatric Units.

THE CENTAURS
OR
SCIENCE AND RULERS*

WALTER ELLIOT
P.C., M.C., F.R.C.P., F.R.S., M.P.

THE Centaurs, half-man, half-horse, represented in egend the union of knowledge and strength. The egend has a special interest for those of us whose study s, or has been, medicine, since Chiron the ancient, the ead of the race, was the teacher of Æsculapius, the ounder of medicine. The thought of these gigantic indly creatures, the guardians of learning, the friends f man, is worth commemorating in a world which has een so many monsters born, not all as lovable. The hief of these monsters, perhaps, is the modern State, he modern conjunction of knowledge and strength.

England has a special interest in all this, because of the orm in which that conjunction presented itself to the mind of one of her great philosophers, Hobbes, still one of the most authoritative writers on the State. Hobbes hought of the State as Leviathan, and made that the itle of his book. Return for a moment to the original exts (in which Hobbes's mind was undoubtedly steeped), and consider Leviathan as he is there described to us:

> "His heart is as firm as a stone: yea, as hard as a piece of the nether millstone. When he raiseth up himself the mighty are afraid; by reason of breakings they purify themselves.
>
> "Upon earth there is not his like, who is made without fear. He beholdeth all high things; he is a king over all the children of pride."

And there is, lastly, the terrible adjuration—

> "Lay thine hand upon him, remember the battle, do no more."

This is much more the conception with which we are familiar nowadays. All the spirit of our time seems to side with the ferocious, the awe-inspiring, Leviathan-ruler, the omnipotent State. Yet perhaps the Greeks had a better word, or at least a better thought, for it.

It is noteworthy that about the Centaurs their second thoughts were best: the original Centaur tales are merely about a fierce shaggy race whose name means "the bull-killers" and who dwelt in the mountains of Thessaly. The benign race, so wise and far-reaching in their knowledge that they knew everything from archery to medicine, and so urbane and well disposed that they asked nothing better than to communicate their knowledge, was a later conception. The Greek legends became more humane as they progressed. It is a view we might strive to imitate.

PHILOSOPHERS AND KINGS

The great strength of the Greek legend is that it recognises, and indeed rather delights in, the thought of this union of strength and science as a benevolent combination, capable of communion with men but remote from them. It was not till the disillusion of Greek thought that it turned to this union as a desirable ruler on earth, the belief that all would be well if kings were philosophers and philosophers were kings.

Robert Louis Stevenson once recoiled from marriage because it was "to domesticate the Recording Angel." In the modern State we tend to domesticate not only the Recording Angel but the Day of Judgment.

Harvey, whom this society commemorates, maintained all through his life the view of government as a diversity rather than a unity, neither seeking to turn Charles the King, his close companion, into a scientist, nor desiring, himself, to be any kind of a king. Today our rulers are becoming most horribly scientific; and some at least of our scientists are becoming so very kingly. It is a mistake.

The danger of the philosopher-king nowadays is, that the mere brute weight of knowledge is becoming so great that by the time a man has tackled it all—and the supreme philosopher can aim at no less—he has lost the power of disbelief altogether. The faculty of disbelief, like every other faculty, atrophies with disuse. Yet it is perhaps the most important single scientific touchstone that man's mind possesses, and it was never more necessary than it is now. The phrase "science tells us" should raise an instant challenge in our minds. Very often, however, it is the prelude to a dumb acquiescence. Add to this the weight of government, and you crush the mind of man into the ground.

Necessary as the power of disbelief is to a scientist, it is even more so to a ruler, and in the fusion it is lost to both. Modern knowledge and modern government are two such immensely powerful things that, conjoined, they flash readily together into tyranny. What is more, they are each so engrossing that each distracts the mind from the other, and you tend to get a figure who is regarded as a terrific philosopher amongst the kings, and a terrific king amongst the philosophers. The mind of the administrator should be a haft, the mind of the scientist should be a blade. Nothing but confusion will result if the blunt haft is continually trying to prolong itself forward to be a blade, and the edged blade continually claiming to be used direct as a haft. This is a plea therefore for the maintenance of these two views, the biaxial eyes of the soul, and for resistance to the tendency to fuse the whole into a single monocular approach. It is worth while remembering, since we are on the subject of legend, that the single eye was the mark of that race of giants whom Ulysses outwitted, the Cyclops, amongst the strongest of beings, but also the stupidest.

Nowadays governments, which is to say the rulers, have to work in, and through, our scientific age. In so doing, philosopher-kings inevitably identify themselves to some extent with some particular set of scientific doctrines. It is very difficult for them thereafter to detach themselves from these doctrines; and the true scientific spirit, the equal delight in being found wrong as in being found right, so be it that knowledge is advanced, gets lost altogether. I do not say that all scientists attain and retain these heights. Von Helmholtz said that he owed his entire scientific reputation to performing the experiments set out as demonstrations in the textbooks, and then seeing why the results there predicted did not happen; but all teachers are not Helmholtzes, and we have often watched the embarrassment and even the indignation of a lecturer in similar circumstances—and indeed may have shared in it ourselves.

LEVIATHAN AND OUR DAILY BREAD

Take one or two examples of this addiction to particular views. Take, for example, contemporary nutrition.

The contention is advanced that the nation is as well fed, or is better fed, as a result of rationing than it was before the war. This should have an objective examination. Adequate feeding is not an abstract but a concrete affair; it is the balance of output against output. It must be effected, for instance, by full employment. The intake for a nation, every person in which is in full activity, must be greater than the intake for a nation in which a significant fraction is running at a low level of muscular activity. To the Centaurs that would have been self-evident. But Hobbes saw more clearly than the fabulists. In the fusion of knowledge with power, it is knowledge that takes second place. Leviathan comes grinding forward—and Leviathan is not a distant creature dwelling in the hollow of the hills.

* Harveian lecture delivered before the Harveian Society of London o

Medical Art Society

This society is to hold an exhibition at 1, Wimpole Street, London, W.1, from July 17 to 26. The secretary is Dr. Henry Wilson, 142, Harley Street, W.1.

Unesco Awards

Unesco has awarded grants-in-aid to 47 scientists in 10 European countries and in the U.S.A., for the purpose of attending the sixth International Congress for Experimental Cytology, which is to be held in Stockholm from July 10 to 17.

L.C.C. and N.H.S. Act

The health committee's proposals for carrying out the London County Council's duties under section 26 (vaccination and immunisation) and section 27 (ambulance services) of the *National Health Service Act* were considered by the council last Tuesday.

Diabetic Association

At 10 A.M. on Friday, July 18, Prof. Charles Best, F.R.S., will deliver the first Banting lecture at King's College Hospital, London, S.E.5. In the afternoon and on the morning of Saturday, the 19th, there will be further lectures and demonstrations in the diabetic and biochemical departments. Doctors and medical students are invited to attend.

Medical Treatment for Civilian Repatriates

Till now civilians repatriated from enemy-occupied territories have been entitled to six months' free medical treatment irrespective of whether their illness was due to their internment or not. These arrangements have now been cancelled (Ministry of Health circular 111/47), but patients whose illness is attributable to their internment will continue to be an E.M.S. responsibility.

Epsom College

Dr. Harold Spitta has been appointed chairman of the council in succession to the late Mr. D. C. Bartley. During the past year the following governors have been elected to fill vacancies on the council: Surgeon Vice-Admiral Sir Basil Hall, Brigadier H. Glyn Hughes, Mr. R. W. Raven, Lieut.-Colonel Sir Bernard Reilly, Dr. Eric Sargent, and Mr. Noel Waterfield. In the report presented at the annual meeting on July 4 it was announced that during the period 1945–47 eleven open scholarships and exhibitions to Oxford and Cambridge had been won. "Successes in the London 1st M.B.," the report continues, "have shown an abrupt decline, not easily to be explained by a falling off in the quality of candidates, since successes in the equivalent examinations at Oxford and Cambridge have remained as high as ever."

Appointments

Brun, Claude, M.B. Lond., F.R.C.S.: accident officer, Salford Health Committee and Salford Royal Hospital joint accident service.
Holden, Herbert, M.B. Lpool: asst. radiotherapist, General Hospital, Northampton.
Rassin, Meyer, M.B. Edin., F.R.C.S.E.: surgeon, West Middlesex County Hospital.
Robson, T. W., M.B. Edin., D.P.H.: deputy M.O.H. and senior asst. school M.O., Reading.
Stengel, Erwin, M.D. Vienna: director of clinical research, Graylingwell Hospital, Chichester.
Watkins-Pitchford, John, M.B. Lond., D.P.H.: H.M. inspector of factories.
Wilson, Elizabeth, M.B. Glasg.: asst. M.O.H. and asst. school M.O., Wigan.

Guy's Hospital, London:

Moynahan, E. J., M.R.C.P.: registrar, dermatological department.
Salmon, L. F. W., M.B.E., M.B. Lond.: specialist in ear, nose, and throat department.
Young, A., F.R.C.S.: specialist in ear, nose, and throat department.

St. Mary's Hospital Medical School (University of London):

Sames, C. P., M.S. Lond., F.R.C.S.: asst. director of the surgical unit.
Stanley, B. E. C., M.B. Lond., F.R.C.S.: asst. in the surgical unit.

North Middlesex County Hospital:

Faux, Nancie, M.B. Lond., D.A., D.P.H.: senior anæsthetist.
Knowles, G. S. A., M.B. Lond., D.A.: senior anæsthetist.
Reid, G., M.B. Edin., F.R.C.S.E.: temporary surgeon.

City General Hospital, Leicester:

Hirsch, W. P., M.R.C.S., M.R.C.O.G.: obstetrical and gynæcological registrar.
Shield, J. B., M.B. Edin., F.R.C.S.E.: chief asst., orthopædic department.

Royal Sanitary Institute

On Saturday, July 12, a meeting of the institute is to be at 10.30 A.M. in the Guildhall, Worcester. Mrs. E. Moore will speak on a Home Help and Domestic Help Se and Mr. T. W. Marsden on Public-health Aspects of Relief.

Return to Practice

The Central Medical War Committee announces Dr. James S. Young, M.R.C.O.G., has resumed civilian p at 57, Harley Street, London, W.1 (Langham 3556).

Diary of the Week

JULY 6 TO 12

Monday, 7th

Royal College of Surgeons, Lincoln's Inn Fields, W.C.2
3.45 P.M. Prof. C. M. West: Anatomy of Circulatory Sy (First lecture.)
5 P.M. Prof. R. A. Gregory: Stomach.
Westminster Hospital School of Medicine, Horseferry R S.W.1
5 P.M. (Meyerstein lecture theatre.) Clinico-pathological demonstration of two cases of aplastic anæmia.

Tuesday, 8th

Royal College of Surgeons
3.45 P.M. Professor West: Anatomy of Circulatory Sy (Second lecture.)
5 P.M. Prof. G. W. Pickering: Nutrition of Heart.
6.15 P.M. Prof. W. K. Livingston: Physiological Respons Wounding. (Moynihan lecture.)
Commonwealth and Empire Health and Tubercul Conference
10 A.M. (Central Hall, Westminster, S.W.1.) Dr. G. J. Whe Dr. F. J. Wiles, Dr. Claude Taylor, Dr. P. V. Benja: Tuberculosis in the Commonwealth, including D Diseases.
2.15 P.M. Mr. Aneurin Bevan, M.P., Dr. Norman Tatte Dr. B. R. Clarke: National Health Service Act (1 —*and its effect on tuberculosis work.*
Institute of Laryngology and Otology, 330, Gray's Inn Road W.C.1
5 P.M. Mr. V. E. Negus: Nose, Nasopharynx, and Para Sinuses.

Wednesday, 9th

Royal College of Surgeons
3.45 P.M. Dr. D. V. Davies: Joints.
5 P.M. Prof. Alan Kekwick: Nutrition and the Surgeon (Prote
Royal Medico-Psychological Association
11 A.M. (Winter Garden, Eastbourne.) Annual meeting.
2.30 P.M. Dr. W. G. Masefield: Presidential address.

10 A.M. Dr. G. S. Todd, Mr. Alexander Gray, F.R.I.B.A., Mi Jane Drew, F.R.I.B.A., *Dr. Robert Cunningham*: Sana torium Design at Home and Abroad.
11.30 A.M. Dr. R. R. Trail, Dr. Etienne Berthet: Care and Rehabilitation Schemes.
2.15 P.M. Prof. W. H. Tytler, Dr. E. R. Long, Dr. A. Q. We Dr. H. C. Hinshaw, Dr. K. N. Irvine, Dr. H. S. Wil: Specific Measures in *Prevention* and *Treatment* of Tuberculosis, Streptomycin, B.C.G., &c.
Medico-Chirurgical Society of Edinburgh
8.30 P.M. (7, Drumsheugh Gardens, Edinburgh.) Prof. J. R. Learmonth, Miss Catherine Burt, Dr. Douglas Matthew: Anticoagulants.

Thursday, 10th

Royal College of Surgeons
3.45 P.M. Prof. H. A. Harris: Limb Plexuses. (First lecture.)
5 P.M. Professor Kekwick: Nutrition and the Surgeon (Water and Salts).
6.15 P.M. Prof. H. Jackson: Rôle of Anatomy in Symptomatology of Lumbar Disk Protrusions. (Hunterian lecture.)
Royal Medico-Psychological Association
10.15 A.M. (Eastbourne.) Dr. Geoffrey Evans, Dr. Noel Harr: Place of Psychiatry in Medicine.
2.15 P.M. Dr. Donald Stewart: Relation of Society to Occupational Health. Dr. J. Thwaites: Psychiatry in Relation to General *Practice*.
Abernethian Society, St. Bartholomew's Hospital, E.C.1
5.15 P.M. Prof. John Fulton: Harvey Cushing and His Books.
Commonwealth and Empire Health and Tuberculos Conference
10 A.M. Dr. F. R. G. Heaf, Dr. N. L. Rusby, Dr. D. R. W. Cow Human Factor—Propaganda, Psychology, Education.
2.15 P.M. Mr. A. Creech Jones, M.P., Dr. C. E. Bevan, Dr. J. G. S. Turner, Dr. W. S. Gilmore, Dr. Edgar Cochrane, Dr. R. J. Snodgrass, Dr. W. J. Vickers: *Colonial Tuberculos* Services.

Friday, 11th

Royal College of Surgeons
3.45 P.M. Professor Harris: Limb Plexuses. (Second lecture.)
5 P.M. Dr. N. F. Maclagan: Liver Efficiency Tests. (First lecture)
Royal Medico-Psychological Association
10.15 A.M. (Eastbourne.) Mr. F. C. Webster, F.R.I.B.A., Dr. J. J. O'Reilly: Planning of Modern Psychiatric Units.

THE CENTAURS
OR
SCIENCE AND RULERS*

WALTER ELLIOT
P.C., M.C., F.R.C.P., F.R.S., M.P.

THE Centaurs, half-man, half-horse, represented in legend the union of knowledge and strength. The legend has a special interest for those of us whose study is, or has been, medicine, since Chiron the ancient, the head of the race, was the teacher of Æsculapius, the founder of medicine. The thought of these gigantic kindly creatures, the guardians of learning, the friends of man, is worth commemorating in a world which has been so many monsters born, not all as lovable. The chief of these monsters, perhaps, is the modern State, the modern conjunction of knowledge and strength.

England has a special interest in all this, because of the form in which that conjunction presented itself to the mind of one of her great philosophers, Hobbes, still one of the most authoritative writers on the State. Hobbes thought of the State as Leviathan, and made that the title of his book. Return for a moment to the original texts (in which Hobbes's mind was undoubtedly steeped), and consider Leviathan as he is there described to us :

> "His heart is as firm as a stone ; yea, as hard as a piece of the nether millstone. When he raiseth up himself the mighty are afraid ; by reason of breakings they purify themselves.
>
> "Upon earth there is not his like, who is made without fear. He beholdeth all high things ; he is a king over all the children of pride."

And there is, lastly, the terrible adjuration—

> "Lay thine hand upon him, remember the battle, do no more."

This is much more the conception with which we are familiar nowadays. All the spirit of our time seems to side with the ferocious, the awe-inspiring, Leviathan-ruler, the omnipotent State. Yet perhaps the Greeks had a better word, or at least a better thought, for it.

It is noteworthy that about the Centaurs their second thoughts were best ; the original Centaur tales are merely about a fierce shaggy race whose name means "the bull-killers" and who dwelt in the mountains of Thessaly. The benign race, so wise and far-reaching in their knowledge that they knew everything from archery to medicine, and so urbane and well disposed that they asked nothing better than to communicate their knowledge, was a later conception. The Greek legends became more humane as they progressed. It is a view we might strive to imitate.

PHILOSOPHERS AND KINGS

The great strength of the Greek legend is that it recognises, and indeed rather delights in, the thought of this union of strength and science as a benevolent combination, capable of communion with men but remote from them. It was not till the disillusion of Greek thought that it turned to this union as a desirable ruler on earth, the belief that all would be well if kings were philosophers and philosophers were kings.

Robert Louis Stevenson once recoiled from marriage because it was "to domesticate the Recording Angel." In the modern State we tend to domesticate not only the Recording Angel but the Day of Judgment.

Harvey, whom this society commemorates, maintained all through his life the view of government as a diversity rather than a unity, neither seeking to turn Charles the King, his close companion, into a scientist, nor desiring, himself, to be any kind of a king. Today our rulers are becoming most horribly scientific ; and some at least of our scientists are becoming so very kingly. It is a mistake.

The danger of the philosopher-king nowadays is, that the mere brute weight of knowledge is becoming so great that by the time a man has tackled it all—and the supreme philosopher can aim at no less—he has lost the power of disbelief altogether. The faculty of disbelief, like every other faculty, atrophies with disuse. Yet it is perhaps the most important single scientific touchstone that man's mind possesses, and it was never more necessary than it is now. The phrase "science tells us" should raise an instant challenge in our minds. Very often, however, it is the prelude to a dumb acquiescence. Add to this the weight of government, and you crush the mind of man into the ground.

Necessary as the power of disbelief is to a scientist, it is even more so to a ruler, and in the fusion it is lost to both. Modern knowledge and modern government are two such immensely powerful things that, conjoined, they flash readily together into tyranny. What is more, they are each so engrossing that each distracts the mind from the other, and you tend to get a figure who is regarded as a terrific philosopher amongst the kings, and a terrific king amongst the philosophers. The mind of the administrator should be a haft, the mind of the scientist should be a blade. Nothing but confusion will result if the blunt haft is continually trying to prolong itself forward to be a blade, and the edged blade continually claiming to be used direct as a haft. This is a plea therefore for the maintenance of these two views, the biaxial eyes of the soul, and for resistance to the tendency to fuse the whole into a single monocular approach. It is worth while remembering, since we are on the subject of legend, that the single eye was the mark of that race of giants whom Ulysses outwitted, the Cyclops, amongst the strongest of beings, but also the stupidest.

Nowadays governments, which is to say the rulers, have to work in, and through, our scientific age. In so doing, philosopher-kings inevitably identify themselves to some extent with some particular set of scientific doctrines. It is very difficult for them thereafter to detach themselves from these doctrines ; and the true scientific spirit, the equal delight in being found wrong as in being found right, so be it that knowledge is advanced, gets lost altogether. I do not say that all scientists attain and retain these heights. Von Helmholtz said that he owed his entire scientific reputation to performing the experiments set out as demonstrations in the textbooks, and then seeing why the results there predicted did not happen ; but all teachers are not Helmholtzes, and we have often watched the embarrassment and even the indignation of a lecturer in similar circumstances—and indeed may have shared in it ourselves.

LEVIATHAN AND OUR DAILY BREAD

Take one or two examples of this addiction to particular views. Take, for example, contemporary nutrition.

The contention is advanced that the nation is as well fed, or is better fed, as a result of rationing than it was before the war. This should have an objective examination. Adequate feeding is not an abstract but a concrete affair ; it is the balance of output against output. It must be effected, for instance, by full employment. The intake for a nation, every person in which is in full activity, must be greater than the intake for a nation in which a significant fraction is running at a low level of muscular activity. To the Centaurs that would have been self-evident. But Hobbes saw more clearly than the fabulists. In the fusion of knowledge with power, it is knowledge that takes second place. Leviathan comes grinding forward—and Leviathan is not a distant creature dwelling in the hollow of the hills.

---

* Harveian lecture delivered before the Harveian Society of London on May 21.

Leviathan is our daily life—Leviathan is the food office, Leviathan is Whitehall. Nay more, Leviathan is the constituencies. Daily bread is no longer the affair of the Deity, or of farmers, or of merchants, or of individuals, or of families. Daily bread has become the affair of Leviathan.

By reasoning we may appeal to Leviathan's intellect, and though it is a small hope it is our only hope. Let us ask him to look at the figures.

The figures seem to show that, before the war, the food-supply for 1937–38 equalled about 51,500 million calories. At 2900 calories per head the requirements were 48,000 million calories. These were the gross rations pre-war. There was on these figures enough to meet the requirements of the whole population. But actual surveys of one kind or another indicated that for the lowest nutritional third of the population (not necessarily the lowest income third) the intake was markedly below this figure. Active steps were taken, pre-war, to accelerate the steadily rising curve of nutrition, both in calories and in protective foods, which had been a feature of our national life during the whole of the present century. These steps were admittedly having an increasing effect. The Combined Food Board in 1944[1] stated that on theoretical grounds average intake requirements (food actually eaten) are estimated at 2550 calories per head per day.

Now the figure of 2900 calories per day (often quoted as the present British intake) is only the gross total of all the present supplies coming forward for civilian consumption divided by all the people in the country, just as in the case of the 2900+ before the war. The actual figures for consumption in the home, taken out for a sample—a small sample—of actual families, were 2390 calories in December, 1945, and 2300 in December, 1946 (Ministry of Food figures).

Compared with the 3500 calories given as required for the actual intake of the most active, the heavily working, section of the population, these average figures show a deficit of 1200 calories a day. These sample dietaries do not cover school or canteen meals. A canteen meal is supposed to contain 600–1000 calories. Even at the higher figure, a canteen meal would only bring the 2300 calorie figure to 3300; which is well under the figure of about 4000, generally taken as the requirement for a man in hard muscular work. The lower figure of 600 only brings the figure to 2900, which is significantly below the figure given by the National Research Council of the United States as the requirement for a "moderately active" adult man. The present rations have to some extent been improved over pre-war, by a higher extraction of flour and greater spread of liquid milk. But in other respects, such as variety, admittedly desirable to promote a high intake, they are deficient.

Special provision has also to be taken into account. Bransby and Magee[2] agree that, even with this, the present rationed foods, since the rationing of bread, do not provide an adequate food intake, and that this has to be made up by the canteen meals, and the "family pool," plus unrationed foods, and a certain gain in calories which can be achieved if points are exchanged into bread units. Allowing full weight for the effect of these factors, in that the rations are surplus to the needs of children under about 12, women, and old people, and that therefore the "family pool" is a real source of surplus food for the "bread-winner," the chief unrationed food is potatoes. The average male would have to eat ½–1½ lb. of potatoes a day to balance his food budget. That is 3½–10½ lb. per week. As the supply of potatoes ran about 5 lb. per week in 1943–44, and certainly has not increased since, the upper limit would require much good fortune to reach, and much assiduity to consume. The manual worker is considered to require up to 14 lb. of potatoes a week. His chances of getting or of digesting them are small. Indeed, catering establishments have requested by the Ministry of Food several times rece to cut down potato consumption by 20%; it would interesting to know whether the health authorities, the fuel authorities, have been in agreement with injunction.

The contention that we are better fed than before the war is therefore certainly a matter for investigation and for further proof. One would expect to find spokesmen of industry, and of industrial Ministries, fighting the question of food intake at every turn, using the present figures to explain and even to justify absenteeism and low output generally, and making the case, which is scientifically true, that the heat-engine of the body cannot do more work than the fuel put into it allows, any more than a car can be made by exhortation to cover the last few miles of its journey on an empty petrol tank. But Leviathan encountered *this problem from the food angle first. Leviathan brings* every ounce of his weight into play to make certain that this aspect prevails. There are many statistics in our national life most creditable to the efforts made to maintain an adequate food intake—the new low levels *for stillbirths and for neonatal, infant, and maternal* mortality. But the very success of these efforts has led to the rations being "pared." Bacon has been recently cut by 1 oz., cheese by 2 oz., and cooking fats by 1 oz. Meat has been increased by 2 oz., but there are apprehensions regarding the continuance of this level and the present provision is admittedly getting "tighter." Full activity for the nation would in fact mean not merely a maintenance but an increase of the gross quantities per head available pre-war. But this is now a matter of polemics, not of science; and where Leviathan enters, polemics are a very one-sided affair. Our nutritional balance-sheet has been brought to a very narrow margin; and it may be that here, as elsewhere, we are drawing upon stocks. There is certainly nothing to spare. Investigation not assertion—the Centaur's approach, not Leviathan's—is urgently required.

LEVIATHAN AND OUR CHILDREN

Take another example. One of the classes traditionally subject to direction is the population of school age. The extension of authority, which is one of the outstanding features of our age, has over many years brought this class in Great Britain into a regimentation not surpassed, and indeed not reached, in any previous time. This has disadvantages as well as advantages. From the medical point of view the close confinement, for many hours a day, of a naturally active and inquiring category of human beings is prima facie a drawback. Furthermore this confinement is not individual but collective. The naturally centrifugal habits of young children are replaced by an extreme centripetalism (We must leave out of account, for the moment, the various reactions of this upon the mind.) Upon the body it has the same effect, for certain reactions, as the herding together of other species. In particular, it exposes them very markedly to mass infection.

I am not unaware of the great benefits which supervision brings to the young, in many cases. It is not, however, all gain—Leviathan is not the ideal nurse. There were advantages in the education of the young Greeks with the Centaurs. It was not a matter of all day and every day in close confinement—and it did not go on for ten years.

As Minister of Health, many problems of public health were constantly thrust on my notice. The problem of epidemics among children was one of the most insistent

---

2. Bransby, E. R., Magee, H. E. *Brit. med. J.* 1947, i, 525.

and the most baffling. Indeed one of the earliest of my memories, as an Under-Secretary, was a long and intense scene in the House of Commons, when James Maxton and several of his colleagues, the Clyde members, were eventually suspended from the House because of their anger over a sharp rise in the Glasgow death-rate due to an epidemic of measles. Eighteen years later this subject came very closely under my notice again, for I happened to be Minister of Health in 1939–40, when, for the first time in half a century or more, a disturbance of the school year was caused, so universal and extensive that it produced many significant results. I refer to the evacuation and dispersal of children at the commencement of the war.

Let me quote from *A Study of Measles* [3] by Dr. Brincker, hen a principal medical officer of the London County Council. He draws attention to the very well-known phenomenon of "the regular series of biennial explosions of measles in London." He quotes Greenwood and Topley [4]:

> "The periodicity of such an epidemic disease as measles is probably due to *periodic changes in the constitution of* the population exposed by risk leading, after each epidemic wave, to a gradual reaccumulation of susceptibles. . . . In the natural world the reaccumulation of susceptibles is by births rather than by immigration; but there are specialized herds, such as schools in general and boarding-schools in particular, in which the immigration of immunes term by term is probably a decisive factor in determining the course of events."

The operative word is "herds." This was long suspected, but no opportunity ever arose to put it to the proof on the grand scale. Not till the evacuation and dispersal, forced on the country in 1939 by the terror of air-bombing. The air-bombing did not actually take place that winter, but the fate of Rotterdam and Warsaw showed how easily the threat might have been fulfilled. It did take place later, though not with the catastrophic suddenness which was one of the main nightmares of those who had to organise measures for the safeguarding of the civilian population in the years immediately preceding 1939. The blitz of 1940–41, and the V.1's of 1944–45, made it necessary to utilise all the mechanism that had been worked out before 1939, and were put into practice in the autumn of that year. The absence of air-bombing, however, in the first evacuation, makes it possible to review it as a purely peace-time operation.

The results of that great movement may be summed up in a few sentences. Dr. Stocks [5] says:

> "Never since 1917 had there been a break in the biennial periodicity of epidemics (of measles) but in the first quarter of 1940, when one was expected to begin, it failed to appear. It is difficult to avoid the conclusion that this was connected with the great and unprecedented reduction of school contact between the children living in London from September 1939 to Easter 1940, and after, as will be seen later."

And Dr. Gale [6] says:

> "It is difficult to make up one's mind exactly how far the reductions in incidence of infectious disease were due to removal of children from the thickly populated evacuation towns with consequent 'thinning' of the child population and how far they were due to school closure. . . . I believe that school closure was a considerably more important factor than 'thinning'."

How important this was, in actual deaths, may be seen from table I.

The tendency, pre-war, for simplicity's sake, may be taken as high in years ending in an even number, and low in years ending in an odd number. The sudden arrest of the biennial swing has produced a lasting effect, and the oscillation, though re-established to some extent, is at an altogether lower level, and has changed to high in odd, and low in even, years. Table II gives the figures for calendar years. I have not been able to give the figures for "winters." An overlook back to 1936 in calendar years is given.

TABLE I—MEASLES DEATHS IN LONDON (ADMINISTRATIVE COUNTY) DURING "YEARS" (OCTOBER–SEPTEMBER) FROM 1922–23 [5]

1922–23 ..	154	1928–29 ..	112	1934–35 ..	10
1923–24 ..	1530	1929–30 ..	1113	1935–36 ..	596
1924–25 ..	117	1930–31 ..	50	1936–37 ..	15
1925–26 ..	1170	1931–32 ..	885	1937–38 ..	245
1926–27 ..	53	1932–33 ..	62	1938–39 ..	2
1927–28 ..	1480	1933–34 ..	906	1939–40 ..	5

TABLE II—MEASLES DEATHS IN LONDON DURING CALENDAR YEARS

1936 ..	584 ..	even	1942 ..	31 ..	even
1937 ..	24 ..	odd	1943 ..	50 ..	odd
1938 ..	235 ..	even	1944 ..	7 ..	even
1939 ..	4 ..	odd	1945 ..	31 ..	odd
1940 ..	29 ..	even	1946 ..	17 ..	even
1941 ..	51 ..	odd			

By the way, in the period 1939–40 the figures were, 5 in London, 2 in Birmingham, 31 in Liverpool, 19 in Manchester, 5 in Leeds, and 3 in Sheffield, 65 in all, as against 617 in the same cities in the previous biennial peak 1937–38. It would not be true to say, without further comment, that owing to the closing of the schools in the autumn of 1939 552 children were alive who would otherwise have been dead, but it is true to say that the deaths of 552 more children from this one disease in 1939–40 would not, pre-war, have been regarded as anything beyond normal. Dr. Gale [6] comments:

> "Closure of the schools over a large area would be, to put it mildly, a highly inconvenient procedure, and the graphs of weekly notifications suggest that unless the period was long enough to extend into the non-epidemic season, the epidemic would start soon after the re-opening. I do not think therefore that the experience of the dispersal upsets the policy which we have been advocating for years of keeping a school open in face of an epidemic. We should however consider the matter of infections spread seriously when the question of post-war design of schools arises. I have wanted to investigate the incidence of infectious disease in open-air schools but have been deterred by the obvious difficulties of devising a control."

It seems clear therefore that as one of the concomitants of education involving "herding," we must expect the destruction of considerable numbers of children. The bearing of this on present-day reforms in education, and particularly on the relative importance of smaller classes—i.e., less herding—as against prolongation of the school age is obviously important. Frankly, it would appear that nothing is so important as keeping down the numbers in classes.

There is much confirmatory evidence on the effects of "herding." Dr. Margaret McLaughlin,[7] in a paper based on 12 months' work in Birmingham day nurseries, concludes that among those presumed susceptible the incidence of measles was four times greater among children in the nurseries than in the corresponding home group. It is worth noting that she also thinks that respiratory-tract infections were from two to eight times more frequent among "nursery" children than among the corresponding home group. This is borne out by the figures for such conditions as adenoids and enlarged tonsils, and lung diseases (non-tuberculous), obtained during the years of dispersal and evacuation in the London administrative county. Adenoids and tonsils, which showed a figure of 9·2% of the children inspected in 1938, showed 9·0% in 1939 and 3·5% in 1940, rising to 5% in 1941. Lung diseases (non-tuberculous) showed 1·5% in 1938, 1·1% in 1939, and 0·6% in 1940, rising to 1·0% in 1941.

[5] Stocks, P. *J.R. statist. Soc.* 1942, 104, 311.

[6] Gale, A. H. *Proc. R. Soc. Med.* 1943, 36, 97.

[7] McLaughlin, M. *Brit. med. J.* 1947, i, 631.

It would not be right to lay overmuch stress on these figures, but they certainly do not contradict those earlier quoted. They all emphasise the importance of the family—the quarrelsome, insulated, isolated, family—to which modern psychologists also begin to bear witness.

Yet on the whole it has been difficult to attract the attention of Leviathan to this aspect. I have read, I suppose, dozens of papers on the impact of evacuation on education, for every one I have read on the impact of evacuation on life. Yet it is clearly important in itself, and not less in its implications, because the effects of herding may not be confined to the obvious results of death-rates from infectious diseases. The psychological results, to which observers of city-bred populations are beginning to call attention, may alas be noteworthy. I was much struck by certain passages in a paper read at a recent conference under the auspices of the Association of Agriculture by Dr. C. S. Flack, headmaster of Aston Commercial School, Birmingham. He pointed out that "in matters of education the limitations of a congested city environment have not yet been sufficiently recognised."

Leviathan however is driving straight ahead and is difficult to turn. We shall be a great deal more congested, both in mind and body, before we are better.

INDEPENDENT INSTITUTIONS

I have given two examples of the pressure of Leviathan, one upon children and one upon adults. I think it urgent, indeed vital, that alternative lines of progress to these derived from such immense pressures—immense, concentrated, pressures—should exist.

I should expect these to be preserved by independent bodies of various kinds, of which the Harveian Society is one. I should expect them to be preserved chiefly by the universities, existing as self-governing independent institutions. The rapid and increasing assistance given by the State to the universities must be judged according to whether it comes from the Centaurs or from the Leviathans, and the recent expansion of the university grants from £2 million a year to something like £9 million is not without its dangers. Even the University Grants Committee, most tolerant of bodies, is drawn into a degree of supervision which may easily defeat its own object, the cultivation of independent thought.

It is easy for the lower forms of life to destroy the higher. Even the Centaurs, flown with wine and insolence, at a marriage feast fell into conflict with their brutish neighbours, the Lapithæ, and were overborne. Nothing either in Hobbes or the *Book of Job* has overborne Leviathan. Let us therefore be wary always.

"... Man is a unique product of evolution in that he, far more than any other creature, has escaped from the bondage of the physical and the biological into the multiform social environment. This remarkable development introduces a third dimension in addition to those of the external and internal environments—a dimension which many biologists, in considering the evolution of man, tend to neglect. The most important setting of human evolution is the human social environment . . . this can influence evolutionary changes only through the media of mutation, selection, genetic drift, and hybridisation. Nevertheless, there can be no genuine clarity in our understanding of man's biological nature until the rôle of the social factor in the development of the human species is understood. A biologist approaching the problems of human evolution must never lose sight of the truth stated more than 2000 years ago by Aristotle: 'Man is by nature a political animal'."—TH. DOBZHANSKY and M. F. ASHLEY MONTAGU, *Science*, June 6, 1947, p. 587.

VAGOTOMY FOR PEPTIC ULCER

THE surgical treatment of peptic ulcer has for its ob the prevention of recurrence in the face of inevit stress rather than the healing of a particular ulcer. relation of exacerbation of symptoms due to pe ulcer to environmental and emotional strain sugg that the hypersecretion of acid and possibly other orders of function predisposing to ulcer formation due to nervous impulses arising in the higher cent That such impulses are carried in the vagus was sh by Pavlov's demonstration that the gastric secretion response to conditioned stimuli is abolished by cutt off the vagal innervation. It is therefore reasonable hope that vagal section in man will abolish that of gastric hypersecretion which is due to nerv impulses and so protect the stomach from psyc stress.

Neither animal experiments nor the earlier attem in man gave any indication that the degree of secretion could be permanently affected by vagotomy. Ferguson (1936) divided both vagi below the diaphrag in monkeys and found that they all developed cardi spasm, and some of them gastric hypotonia, but in case was there any reduction in the acid response to test-meal. Hartzell (1929) reviewed the literature vagotomy and described experiments in which the vag were divided in dogs, some above and some below the diaphragm. He found that the acid response to a test meal fell, there being an increase in pH of 1·5–2 units; in a dog in which one vagal trunk was not divided the acidity did not fall. Vanzant (1931) re-examined four of Hartzell's dogs $2^1/_2$ years later and found that the acid values had returned to their preoperative level. Shapiro and Berg (1932) studied the gastric acidity after a test meal in a Pavlov pouch and in the main stomach in five dogs before and after partial gastrectomy and division of the vagi below the diaphragm: they found that the acid values were depressed for 2–4 weeks but then returned to their previous level.

Attempts to treat peptic ulcer in man by vagotomy are reviewed by Hartzell (1929); all the writers cited by him used the abdominal route. Pieri and Tanferna (1930) performed section of the left vagus in the chest in two cases, and of all vagal branches below the diaphragm in three. They found a reduction in the acid response to an Ewald meal, but at follow-up investigations at intervals of up to 18 months the acid values had returned to their preoperative level. Weinstein et al. (1944) review the subject of vagotomy before 1938 and emphasise that all authors relied on a partial section They describe two intrathoracic vagotomies in man which they thought at the time were complete: one patient died of adrenal hæmorrhage and was found at necropsy to have 20–40% of his vagal fibres still intact, and the other was shown to have intact vagal fibres by the hypoglycæmia test (see below). They say that "it is far from simple to expose all sides of the œsophagus. . . Many of the smaller fibres will escape the most determined operator." This review leads to the conclusion that section of the vagi below the diaphragm is incomplete, and that incomplete vagal section is not effective in permanently lowering acid secretion.

The first consistently successful vagotomies are reported by Dragstedt and Schafer (1945), Dragstedt (1945), and Thornton et al. (1946). They use the left nspleural approach and take care to mobilise a portion the œsophagus and define all branches of the vagal :nks. They emphasise that some fibres enter the ophageal muscle and travel in it down to the stomach ; tion of two trunks is no guarantee that a complete gotomy has been performed.

These anatomical facts presumably explain the failure vagotomy in the past. The section below the diaphragm it has usually been performed is inadequate, but these thors have done five vagotomies from the abdomen making an incision in the diaphragm and mobilising portion of the œsophagus from below; this was mbined with gastro-enterostomy in cases where there s pyloric obstruction.

These workers have reported their experiences with irty-nine patients; one died of bronchopneumonia m aspiration of material vomited after operation; ey now make it a point to aspirate the stomach ntinuously for 3 to 4 days until the transient gastric ony has passed off.

Thirty cases of duodenal ulcer gave almost uniformly tisfactory results over periods of up to 3 years. In e of two cases of gastric ulcer healing was progressing t incomplete after 6 weeks. Seven cases of anasto-otic ulcer were less satisfactory, and two required further atment.

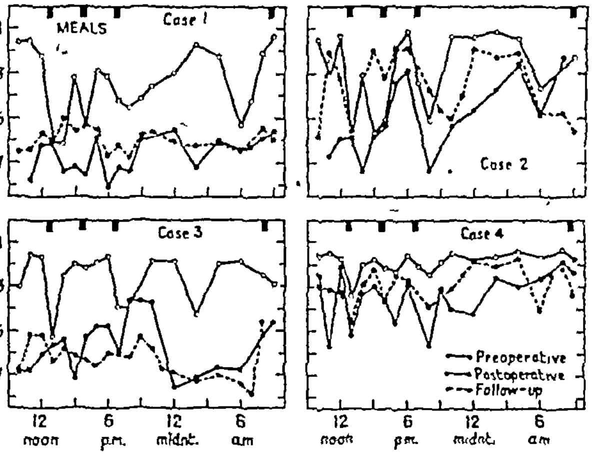
Before operation the average total volume of night cretion was 821 c.cm. and free acidity 47 c.cm. N/10 OH per 100 c.cm. The corresponding figures after eration were 335 c.cm. and 15 c.cm., which are com-rable with figures obtained from patients with unrelated nditions. The secretory response to histamine is affected by vagotomy; the secretory response to poglycæmia produced by insulin was abolished in all ses, and this is regarded as a test of complete vagal ction.

Results in fifteen cases are reported by Moore et al. 946). There were no fatalities and no recurrences in e whole series. To test the ability of the operation to revent recurrence, no dietary restrictions were imposed n the patients. Samples of gastric juice were withdrawn intervals of 2 hours during periods of up to 48 ours and showed considerable reduction in acidity; ough most patients showed a pH of 1·0 at some me during the night, in no instance after operation d the pH fall below 1·5. So far as the follow-up exami-ations were taken, no tendency was noted for the acid alues to return to their previous level.

Encouraged by the report of Dragstedt and Schafer 945) we have performed the operation on four patients ith severe and recurrent peptic ulceration. The cases e chose were all characterised by an excessive secretion acid sustained throughout the 24 hours, and we lt that the success of any operation must be judged rgely by its effect on this secretion. There are cogent asons for believing that the level of intragastric cidity plays some part in determining whether an ulcer eals or recurs, and it is known that the degree of acidity the stimulus to pain in patients with active ulcers Bonney and Pickering 1946).

CHEMICAL INVESTIGATION

To measure the values of intragastric acidity under onditions as normal as possible a Ryle tube was passed nto the stomach, usually through the nose, and left in lace for 24 hours; specimens of gastric juice (about 5 c.cm.) were withdrawn at hourly intervals during the ay and 2-hourly intervals at night. The patient ontinued to eat his ordinary four meals daily under the leulengracht régime and, except the first two tests in ase 1 and the first test in case 2, received no alkali uring the test. The pH of each specimen was determined lectrometrically on the unfiltered juice with the double quinhydrone electrode. Electrometric determination of acidity was chosen rather than titration, because there was sometimes insufficient juice for titration and the presence of food and coloured matter rendered the end-point uncertain. To judge the accuracy of the electrometric method, fifteen determinations were made on a single specimen, and the standard deviation was found to be 0·067 pH units.



Results of 24-hour acid tests in cases 1–4.

The 24-hour test was performed shortly before operation and after recovery. It has also been carried out at follow-up examinations at different intervals after operation.

CASE-RECORDS

Case 1.—Male, aged 44, clerk.

10 years ago: epigastric pain, starting just before meals, relieved by food and alkali; periods of freedom of several months. Radiography showed duodenal ulcer.

18 months ago: partial gastrectomy; large duodenal ulcer found.

9 months ago pain started under right costal margin, relieved by food, alkali, and vomiting.

6 months ago. readmitted; pain and vomiting persisted 3 weeks and then relieved by continuous nocturnal milk drip. Radiography showed irregularity in region of stoma. Discharged after 2 months to continue with milk drip at home.

1 month ago: readmitted with recurrence of pain; laparotomy showed a large stomal ulcer adherent to liver, and no resection could be undertaken.

Vagotomy was performed on Dec. 11, 1945. Milk drip discontinued at once. Discharged free of symptoms after 5 weeks.

When seen again a year after operation, feels well, no pain, excellent appetite, and weight steady; has returned to work.

Case 2.—Male, aged 56, filler of gas cylinders.

10 years ago: perforated duodenal ulcer. A month after operation epigastric pain began, coming on 1–$1^1/_2$ hours after meals and at night. Relieved by food and alkali. Attacks persisted in spite of dietetic treatment.

5 months ago: admitted to hospital with severe pain. Radiography showed deformed duodenum; became symptom-free on Sippy diet and was discharged after a month.

1 month ago: readmitted as pain had recurred 2 weeks after discharge.

Vagotomy was performed on March 12, 1946. Discharged free of symptoms, and receiving no alkali, after a month.

When seen again 6 months after discharge, states he has had no further pain and takes powder only if he is constipated. Can eat anything, feels very well, and has put on 8 lb. Returned to work a month after discharge.

Case 3.—Male, aged 38, truck-driver.

25 years ago: began to have attacks of epigastric pain and vomiting; pain relieved by alkali.

19 years ago : chronically inflamed appendix removed for attacks of pain in right abdomen.

9 years ago : severe recurrence of epigastric pain ; treated in hospital ; well for 8 months, then relapsed.

6 years ago : admitted to hospital with severe pain ; radiography showed duodenal ulcer, and a test-meal "an extremely high curve." Partial gastrectomy was performed.

5 years ago : readmitted with pain in distribution of left 7th and 8th thoracic nerves ; a lump appeared beneath left costal margin ; laparotomy showed a large anastomotic ulcer, which was resected.

$4^{1}/_{2}$ years ago : vomited 2 pints of blood.

4 years ago : perforated a gastric ulcer proximal to the anastomosis.

$3^{1}/_{2}$ years ago : readmitted for attacks of pain ; relieved by gastric aspiration. Continuous nocturnal aspirations maintained at home for a year, during which he was admitted once for melæna.

$2^{1}/_{2}$ years ago : readmitted with severe pain not relieved by powder ; barium meal showed anastomotic ulcer with leakage of barium into peritoneal cavity. Aspirations were continued ; volume of nocturnal aspirate 400–1400 c.cm., with free acidity of 60–70 c.cm. of $N/10$ NaOH per 100 c.cm. ; pain continued. Started on continuous nocturnal milk drip of $1^{1}/_{2}$ pints milk containing 5 oz. 'Aludrox.' Continued milk drip at home for 2 years and remained free of symptoms.

6 months ago : attack of melæna ; readmitted.

Vagotomy performed on April 23, 1946. The milk drip and all alkali treatment were discontinued at once. Was discharged after 6 weeks.

When seen 4 months after discharge, no further epigastric pain ; feels very well, and has taken no alkali. Returned to work 4 weeks after discharge.

Case 4.—Male, aged 45, warehouse dispatch manager.

15 years ago : attacks of epigastric pain began, coming on at any time of day or night, relieved by alkali ; periods of freedom shortened progressively and now last only 3 or 4 days. Taking very large amounts of alkali ; vomiting very rare.

3 months ago : admitted to hospital with severe pain. Radiography showed a long J-shaped stomach with a deformed duodenal cap and a small pyloric niche ; no evidence of pyloric obstruction.

Vagotomy performed on June 18, 1946. Seven days after operation the stomach was dilated, and persistent vomiting began ; relieved by continuous aspiration for 24 hours. Discharged after 5 weeks.

When seen again 4 months after discharge, says he feels better in every way and can eat anything ; has put on 16 lb. As the barium meal showed an uncertain pyloric niche, he was gastroscoped by Mr. J. C. Goligher, and a good view of the pylorus was obtained ; there was no evidence of an ulcer or of any scarring.

OPERATIVE TECHNIQUE

The nerves are divided as they course down the œsophagus from the lower border of the hilum of the lung to the cardia. The œsophagus can be exposed in this position from the right or left side of the chest. On the left side it is overlapped by the aorta, but on the right it is lying immediately under the pleura and is thus more easily accessible. In case 1 the approach was made from the left side, but in the other cases the œsophagus was exposed from the right.

The patient is placed in the lateral position, and the thorax is opened through the bed of the ninth rib after resection. Wide exposure is obtained with a rib spreader. The pulmonary ligament is divided, thus opening the mediastinal pleura, and the lower lobe of the lung is displaced upwards and packed off. The œsophagus is then raised from its bed, and a piece of tape is passed round it to act as a retractor. The main trunk of the right vagus is easily identified below the hilum of the lung ; it is divided, and the proximal end is ligated. Artery forceps are put on the distal end. By rotating the œsophagus the main trunk of the left vagus is discovered and similarly treated. As the trunks are traced downwards they are found to divide to form a plexus surrounding the œsophagus, and branches from the plexus pierce the muscular walls. The whole plexus is carefully dissected downwards to the diaphragm and removed, all branches entering the œsophagus being divided. A search is then made for any branches that may have come from the main trunks above the point of division. If found these must be divided. The œsophagus is then replaced in its bed and the overlying pleura sutured. The lung is distended by the anæsthetist and the chest is closed.

Postoperative management.—From the first the patient requires the care usual after an intrathoracic operation, the object being to restore full pulmonary function as soon as possible. He is encouraged to cough and is given breathing exercises. A pleural effusion usually develops and will require two or three aspirations. A careful watch should be kept for dilatation of the stomach and, if it develops, gastric aspiration should be instituted.

DISCUSSION

The results of the pH determinations show that a very great reduction in acidity follows vagotomy. The figure shows the results of the 24-hour tests. The preoperative test was performed within 2 months of operation. The postoperative test was done from a month to 6 weeks after operation, and the follow-up tests as follows :

Case 1 .. 11 months after operation.
Case 2 .. 7 „ „ „
Case 3 .. 6 „ „ „
Case 4 .. 4 „ „ „

It should be realised that pH is a logarithmic measurement (being log.$_{10}$ of the reciprocal of the hydrogen-ion concentration expressed in g. per litre), that an increase in pH of 1 unit therefore represents a tenfold reduction in acidity, and that the pH number increases as acidity is reduced, pH 7 being neutral, and pH 1·0 about equivalent to decinormal acid.

The parietal cells secrete hydrochloric acid at a concentration which renders the secretion isotonic with plasma, actually 0·17 molar (Hollander 1934). Such a solution has a pH of about 0·91, which therefore represents a theoretical maximum of the acidity of any gastric juice. In actual practice we have found it rare to encounter a juice more acid than pH 1·1 ; in this respect our experience therefore differs from that of Moore et al. (1946).

In our four patients the reduction in hydrogen-ion concentration following the operation was much greater in the two patients with stomal ulcers following gastrectomy than in those in whom the stomach was intact. In fact in cases 1 and 3 (both anastomotic ulcers) most of the postoperative acid values are near neutrality or even on the alkaline side of neutral. This great reduction in acidity we are inclined to ascribe to increased regurgitation of jejunal contents ; possibly the reduction in motility and in the volume of gastric secretion, as demonstrated by Dragstedt, facilitates more effective regurgitation.

In cases 2 and 4, where the stomach is intact, the acidity is reduced but still follows the general trend of the preoperative curve ; it is also notable that the follow-up investigations show a tendency for the acidity to return to its preoperative level.

The possibility that the relief of symptoms is due simply to section of the pain-bearing afferent fibres is discussed by Moore et al. (1946). They claim to be able to produce pain in the stomach by distending it with a balloon after vagal section. We have made no observations on this point but agree that the beneficial results the operation can hardly be due simply to section of e pain fibres.

It is remarkable that the abdominal vagus can be t without untoward results. Dilatation of the stomach me on after operation in case 4 but was soon overcome y gastric suction. Constipation does not result from e operation; in fact there may be some improvement an irregular bowel habit.

For many years operations for the relief of ulceration ve been regarded as physiological rather than anatomi- l. This claim was made for gastrojejunostomy, but e results have led surgeons to shun the operation except patients with pyloric obstruction and low gastric idity. Even partial gastrectomy is followed by recur- nt ulceration in some patients, and in others it is llowed by severe anæmia.

Vagotomy is perhaps the most physiological operation r ulcer yet devised. Its immediate success in the relief f symptoms has been proved; its lasting success must emain a matter of doubt until further time has elapsed nd more experience has been gained. Late results em to depend on two questions: (1) whether the peration can succeed in preventing regeneration of the agal nerve supply to the stomach; and (2) whether e stomach can recover its hyperacidity without egeneration of the nerves.

Only four cases are reported. They were selected for gotomy because they were extreme examples of the er diathesis and three of them had been abandoned considered unsuitable for any gastric operation by dominal surgeons. The history in case 3 is a record pain and catastrophe over many years. The most iking effect of vagotomy has been the gratitude of the tients, who have not experienced such comfort and lief for years. Postoperative investigations gave an lequate explanation for the symptomatic relief. Later llow-up investigations have shown a tendency for the stric acidity to rise again, but in no case has it reached e preoperative level, and relief of symptoms has been aintained without any dietary precautions. These sults support the claims made for vagotomy by other orkers. It is too early to draw final conclusions, but e operation carries a very small operative risk and ould at least prove to be a useful and successful adjunct the treatment of a very distressing condition.

SUMMARY

The literature of vagotomy for peptic ulcer is eviewed.

The clinical histories of four patients on whom this peration has been performed are described. All have xperienced symptomatic relief.

Measurements of the gastric pH before and after peration show a substantial reduction in acidity.

A brief description of the operative technique is given, nd the place of vagotomy in the treatment of peptic lcer is discussed.

We wish to thank Prof. G. W. Pickering for his helpful nterest and criticism.

TREATMENT OF THE BLADDER AFTER SUPRAPUBIC CYSTOSTOMY

P. W. Nathan
M.B. Lond., M.R.C.P.
From a Neurosurgical Unit

During the campaign in Italy the two neurosurgical units of the British Army in that country received many cases of traumatic paraplegia or paraparesis. When these cases became numerous, the problems of the treatment of the bladder in which a suprapubic cystostomy had been performed urgently demanded a solution. As there is no generally accepted treatment for the bladder with an indwelling suprapubic catheter, the following investigation was undertaken.

TREATMENT

The treatments investigated fall into three groups: (1) mechanical treatment, (2) sulpha chemotherapy, and (3) combined mechanical and sulpha chemotherapy. A fourth, control, group consisted of patients having no treatment and those having penicillin intramuscularly. The latter category of control was necessary, because many of the patients were receiving at the time penicillin for the wounds involving the meninges, and it seemed possible that this might have had some effect in sterilising the urinary tract.

MECHANICAL

(1) *Tidal drainage.*—The apparatus used was that described by Lawrie and Nathan (1939). It was attached to the suprapubic catheter. This method has the disadvantage that, for a few days after the catheter is changed, there is leaking round the catheter whenever the pressure rises. The irrigating fluid used in all the mechanical methods was either proflavine sulphate 1 in 10,000 in isotonic saline, or neutralised acriflavine 1 in 5000 in isotonic saline; the relative value of these two solutions was not investigated.

(2) *Tidal drainage with acid buffered solution.*—It was thought that, if the urine could be kept sufficiently acid (or sufficiently alkaline), bacteriostasis might be maintained. The strengths of solutions were found which were necessary to maintain the urine at pH 5·2 for three hours and at various values of pH above this. When it soon became obvious that this was an inefficient method of controlling infection, an attempt was made to combine the buffered acid solution with a solution of mandelic acid; but by this time other methods had proved much more successful, so this was abandoned.

(3) *Washouts.*—These were done three times a day with the solutions mentioned. Washing out was continued until the returning solution was free from particles when held up in a glass; the bladders were washed out in short sharp gushes with a bladder syringe. In all these cases, besides the suprapubic catheter, a thin soft very flexible tube was left in the suprapubic stoma; this was inserted before the catheter, so that its end would lie on the floor of the bladder. In washing out, the syringe was connected to the fine rubber tube, so that the fluid rushing out of it would stir up the sediment on the floor of the bladder and would then pour out unimpeded through the relatively large de Pezzer or Malecôt catheter. The solution was used at body temperature. When draining, the catheter was connected by tubing to a bottle attached to the bed at pubic level; this system was sterilised, the neck of the bottle being plugged with cotton-wool.

The washouts were done by R.A.M.C. orderlies. Though this was necessary because of the amount of work falling on the shoulders of doctors and nurses, it was considered that such personnel was typical of the personnel throughout the British and other armies, and was like the nursing staff which these patients would be under for years to come on return to the U.K. The point in the investigation was not to find out an ideal treatment under perfect conditions, but to work out the best and most practical treatment under the conditions reigning in the hospitals abroad and at home.

(4) *Combined washout and tidal drainage.*—The defect of tidal drainage seemed to be that it was too gentle; a sediment always remained at the base of the bladder which was not washed out during siphonage. The apparatus was therefore

modified so that it could be combined with washouts by syringe. This was done by syringing through the thin rubber *tube mentioned above;* the glass connexion of the lead-in tube of the tidal-drainage apparatus was replaced by a glass Y-tube, so that, when the bladder was being washed out, the fluid could flow out of the one arm of the Y, while the other remained in the circuit of the tidal-drainage apparatus, clipped off.

MECHANICAL TREATMENT AND SULPHA CHEMOTHERAPY

(5) *Tidal drainage and sulphanilamide* (2 g. per day): this small dose was tried, as in the intact bladder it is usually sufficient to clear an infection.

(6) *Tidal drainage and sulphadiazine* (6 g. per day).

(7) *Washouts and sulphathiazole* (6 g. per day).

(8) *Washouts and sulphadiazine* (6 g. per day).

SULPHA CHEMOTHERAPY ALONE

(9) *Sulphanilamide* (2 g. per day).

(10) *Sulphathiazole* (6 g. per day).

(11) *Sulphadiazine* (6 g. per day). In many cases, for the first few days after wounding, more than 6 g. of sulphadiazine was given. This was because of the wound involving the spinal cord or meninges, and not because of the bladder. From the point of view of this investigation it is of no importance, as the results of giving 6 g. or of giving more than this are the same.

(12) *Sulphadiazine* (4 g. per day).

CONTROLS

(13) No treatment.

(14) Penicillin only, by intramuscular injection.

RESULTS

The effect of treatment was judged by (1) the amount of pus; (2) the presence of constitutional signs of infection which could be attributed to a urinary infection; and (3) the amount of bacteria.

The amount of pus was considered a better criterion than the amount of bacteria. The indication of the nocuous effects of bacteria on the mucosa is shown by the amount of pus formed. It seems that the presence of *Bact. coli* or of a non-pathogenic staphylococcus is not in itself harmful. It sometimes happened that, though no organisms could be grown from the urine which contained no pus when aspirated from the bladder, the urine taken out of the bottle attached to the bed grew *Bact. coli.* Swabs taken from the inside of the tube attached to the catheter within twelve hours or so of boiling often grew *Bact. coli*, streptococci, staphylococci, and diphtheroids; and swabs of the suprapubic wounds would grow various organisms. As, then, the environment of the bladder often contained more organisms than the urine from the bladder, it seemed that the number of leucocytes was a better criterion of urinary infection than was the number of bacteria. Also a leucocyte count is more feasible than an attempt to grade the number of bacteria present. The urinary leucocyte counts were performed on a specimen of uncentrifuged urine taken from the suprapubic catheter; it was performed by counting the number of cells seen in a field under the low power; twenty fields were counted.

TABLE I—SEPARATE RESULTS OF ALL METHODS OF TREATMENT USED

Method of treatment	No. of cases			
	Bad group	Good group	Best group	Total
(1) Tidal drainage	4	0	0	4
(2) Tidal drainage with acid buffered solution	1	0	0	1
(3) *Washouts*	3	0	1	4
(4) Combined washout with tidal drainage	1	1	0	2
(5) Tidal drainage and sulphanilamide	1	0	0	1
(6) *Tidal drainage and sulphadiazine*	0	1	1	2
(7) Washouts and sulphathiazole	0	1	0	1
(8) Washouts and sulphadiazine	0	0	2	2
(9) Sulphanilamide 2 g. ..	0	2	0	2
(10) Sulphathiazole 6 g... ..	0	0	2	2
(11) Sulphadiazine 6 g.	1	2	12	15
(12) Sulphadiazine 4 g.	0	0	2	2
(13) No treatment	3	0	0	3
(14) Penicillin intramuscularly ..	4	0	0	4
Total	18	7	20	45

The twelve methods of treatment and the two contr have been placed in three groups—bad, good, and b The criteria for these groups are:

Best Methods.—The urine was sterile on culture and contained no leucocytes. Also included in this group are the *cases in which there were less than 10 leucocytes* per

Good Methods.—In this group were placed those wh showed 10–20 leucocytes per field, or in which the patholo reported "occasional leucocyte."

Bad Methods.—In this group were placed those which sho 20 or more leucocytes per field, or what was reported a "pus plus plus," "moderate pus," or "albumin plus plu All those showing constitutional signs of urinary infection w placed in this group.

Table I gives the number of cases for each form treatment which come into each group of results. obtain significant results from so few cases, they will considered in four groups only. Table II shows results collected into the four treatment groups.

TABLE II—RESULTS IN GROUPS OF METHODS

Group	No. of cases treated				
	Mechanical	Combined	Chemotherapy	Control	Tot
Bad ..	8	2	1	7	1
Good ..	0	3	4	0	
Best ..	1	3	16	0	2
Total	9	8	21	7	4

It will be seen that the control group (no treatm and penicillin only) falls entirely into the bad catego

Mechanical methods proved no better than the cont methods. In addition to the figures given in the tabl it must be pointed out that only 3 cases of the ent *series had fever attributed to urinary infection, and* al were in the mechanical treatment group. It may the fore be concluded that mechanical methods of treatme *are more harmful than no treatment at all.* The tables a show that combining a mechanical method with chem therapy detracts from the success of the chemotherapy

Four-fifths of those in the best group were th treated by chemotherapy. When it is remembered th for cases to be placed in this best group the urine had be sterile or had to contain less than 10 leucocytes p field, it will be realised that we have in the sulpha dr an efficient means of dealing with urinary infection the paralysed bladder. Sulphathiazole and sulphadiazi *seem to be equally good, 4 g. in twenty-four* hours bei sufficient.

Further information may be obtained by consideri a few of the cases in greater detail. It was fou that sulphadiazine always cleared a *Staph. aur* infection. A *B. proteus* infection developed in only of the 45 cases, the one treated by tidal drainage wi solution buffered at 5·2. While having the bladder ir gated with this acid solution the patient developed fev which immediately ceased when this form of treatme was stopped.

Patients having what is apparently inadequate trea ment do not always suffer from it.

One patient reached the neurosurgical base fifty days af the onset of the paraparesis. *For the first month of this ti* he had had one or two washouts a week with Duke's apparat and for the last ten days a washout three times a day wi a funnel and tube. His urine showed only 2 leucocytes f field, contained no albumin, and grew *Bact. coli* only.

Once the bladder is free from infection, there bei no leucocytes and the urine being sterile, one cann cease giving sulphadiazine.

In 4 cases with sterile urine and less than 10 leucocyt per field sulphadiazine was stopped and no treatment w given. In the first case, *Bact. coli* was grown from the uri on the third day; on the seventh day hæmolytic streptococ were also grown the patient was then given sulphadiazi in: after a week of this, no leucocytes were found in enty fields; culture still grew *Bact. coli* but no hæmolytic eptococci. In the second case a week after sulphadiazine s stopped the urine contained much pus. In the third case r days after sulphadiazine was stopped there was a slight ection. In the fourth case eight days after sulphadiazine s stopped there was a *Bact. coli* infection, with a moderate ount of pus.

Sulphadiazine was given in doses of 6 g. in twenty-four ours; no patient had this for more than three weeks.

One case raised the question whether this prolonged adminiration of a large dose damaged the bladder mucosa: while e catheter was being changed after three weeks' sulphaazine, a semi-organised shred was found, which was shaped e the bladder and microscopically seemed to be thick mucus. he sulphadiazine was reduced to 4 g. in twenty-four hours; e urine continued to consist of thick glairy mucus, though contained less than 6 leucocytes per field and grew only *act. coli*. No other case having sulphadiazine for three weeks owed any ill effects.

The leucocyte count remained normal, and there were o symptoms or signs of blockage of the renal tubules. æmaturia or renal pains have been seen in patients aving larger doses of the drug, but were never seen in atients having 6 g. in twenty-four hours. But with this ose of sulphadiazine or sulphathiazole, sulpha crystals ere often found in the urine.

Owing to regular evacuations of cases to the United ingdom, no case was seen for longer than fifty days. herefore this investigation was of the treatment of the rinary tract in the first few weeks of paraplegia *only*. n this time it is clear that the best method of treatment f the bladder after suprapubic cystostomy is to give al sulphadiazine. It remains to work out the length time for which this drug can be given and the minimal ecessary dose. Here, not less than 4 g. in twenty-four ours was tried; but half this or less may be adequate.

Siegel (1945) has shown that with 2 g. per day, a blood vel of 3·2–13·9 mg., with an average of 7·2 mg., per 100 ml. obtained, and that with 1 g. the blood level is 1·7–8·1 mg., ith an average of 3·5 mg., per 100 ml.

Prolonged administration of small doses of sulphadiazine o vast numbers of men has been reported by Coburn (1945). e gave sulphadiazine 1 g. daily to 300,000 U.S. Naval ersonnel for 3–6 months. With this dose he found no renal omplications, a mild dermal reaction in 0·5%, "severe lphonamide diseases" (exfoliative dermatitis or granuloytopenia) in 1 in 10,000 men. He also found that, with such dose, sensitisation to the drug was not produced, nor was the evelopment of drug-fast organisms shown; those cases which, n spite of this prophylactic dose, got an upper respiratory ract infection with hæmolytic streptococci reacted entirely ormally to the routine therapeutic dose of the drug.

Coburn showed that this dose (1 g.) of sulphadiazine was n excellent prophylactic against infective respiratory disrders: the number of patients admitted to hospital per onth for respiratory disorders was 5–18 in his 300,000 conrols, but less than 1 in the 600,000 having daily doses of ·5 g. or 1 g. This prophylactic effect is relevant to cases of araplegia, which are liable to succumb to respiratory infecions, if they escape death from urinary tract infection.

Lehr (1945) has shown that sulphacetamide is far less oxic than sulphadiazine or sulphathiazole. He never found vidence of renal damage in rats receiving enormous doses f this compound. It has the great advantage that it is ighly soluble in acid urine.

The success of oral sulphadiazine in controlling urinary infection in the paralysed bladder raises the question whether this form of treatment has not rendered obsolete all mechanical forms of treatment, such as tidal drainage and washouts. This applies to all cases where there is an indwelling catheter and to all cases before and after prostatectomy; in these old bronchitic subjects the prophylactic effect of the drug on the respiratory tract is an additional reason for preferring it. It remains also to investigate the newer sulpha drugs, sulphamerazine and sulphamezathine.

SUMMARY

An investigation of various forms of treatment of the bladder after suprapubic cystostomy was undertaken.

With mechanical methods, which included tidal drainage and washouts, the results were worse than in controls having no treatment.

The effects of sulphonamide therapy were excellent. Sulphadiazine and sulphathiazole were more satisfactory than sulphanilamide, and can be given in small doses with safety for six months.

I take this opportunity of thanking Mr. F. J. F. Barrington, who helped me with advice and criticism.

INTRAVENOUS ADMINISTRATION OF IRON

JOSEPH A. NISSIM
M.B. Lond.
LATE RESIDENT MEDICAL OFFICER, NORTH STAFFORDSHIRE ROYAL INFIRMARY, STOKE-ON-TRENT

IRON is well known to be toxic when administered parenterally. The toxic effects arise from precipitation of iron in the blood, producing multiple pulmonary and sometimes systemic emboli, with symptoms resembling those of fat-embolism; from irritation of the gastrointestinal tract, giving rise to diarrhœa and vomiting, and from depression of the central nervous system, which may lead to coma and death (Heath et al. 1932, Goodman and Gilman 1941, Best and Taylor 1943).

The lethal dose for an animal is given by Best and Taylor (1943) as 30–60 mg. of metallic iron per kg. of body-weight. If this holds good for man, the lethal dose for an adult weighing 70 kg. would be 2–4 g. Toxic symptoms, however, appear long before this dose is reached. The maximal dose of injectio ferri *B.P.* is gr. $^1/_{10}$ (6 mg.). Heath et al. (1932) gave 15 patients with hypochromic anæmia a daily dose of 32 mg. of iron intramuscularly, in the form of iron and ammonium citrate, for about ten days, and found that 96% was utilised in the formation of hæmoglobin; with this dose there were prohibitive toxic reactions.

The work of McCance and Widdowson (1937, 1938) and of Hahn and Whipple (1936) has shown that a daily intake of 5–8 mg. is required to keep a normal man in iron equilibrium. Young children, however, require considerably more iron (as much as 0·6 mg./kg. of body-weight). Women, up to the climacteric, require from two to four times as much iron as men do. Leverton and Roberts (1937) have shown that normal young women need about 16 or 17 mg. daily. Pregnant women require about 20 mg. of iron daily. The average daily needs of those who require iron most is therefore about 15–20 mg. To raise the hæmoglobin of a patient by 1% about 25–30 mg. would be needed. Another 15–20 mg. would have to be added if enteral supply or absorption is deficient. If this amount, which is over double the usual permitted dose, was given daily it would take fifty days to raise the hæmoglobin from 40% to 90%. For these and other obvious reasons, the parenteral use of iron in anæmia has been extremely limited.

To probe the question further, the administration of iron by intravenous infusion was tried at this hospital. For this purpose two different solutions were used:

(1) A sterile solution of colloidal ferric hydroxide prepared from material supplied by Messrs. Evans Medical Supplies Ltd.

ELECTRO-ENCEPHALOGRAPHIC CHANGES IN MIGRAINE

REVIEW OF 51 CASES

D. J. Dow
M.A., B.Sc. Oxfd

C. W. M. Whitty
B.M. Oxfd, M.R.C.P.

From the Nuffield Departments of Neurology and Neurosurgery, Radcliffe Infirmary, Oxford

We have reason to expect electro-encephalograms (E.E.G.) to show a persistent generalised dysrhythmia more often in migrainous than in normal subjects for migraine and epilepsy are genetically associated. Ulrich (1912) found a family history of epilepsy in 20% of 500 cases of migraine. Turner (1907) found the smaller but still significant proportion of 4·3%. Conversely, Cobb (1932) found that 4·3% of 1086 epileptics had migraine, compared with 1·5% of 250 normal controls. Many other workers have demonstrated a similar relationship.

The E.E.G. data on this point vary considerably. Reviews of the clinical use of E.E.G. (Williams 1945, Gibbs and Lennox 1944) do not refer to migraine. Gibbs et al. (1937) mentioned 2 cases in which "significant changes in E.E.G." were recorded after intravenous ergotamine tartrate, but gave no further details. Strauss and Selinsky (1941) found abnormal records between attacks in 4 of 20 cases, but 2 of the 4 patients were also epileptic. No change was found in "resting" records taken during migraine. But in 5 cases with normal records overbreathing produced generalised abnormal slow-wave activity only during migraine. In 2 of these ergotamine tartrate abolished both the headache and the abnormal response to overbreathing. Harty et al. (1942) found 11% of abnormal E.E.G. in U.S. Army recruits with recurrent headaches but without neurological signs. Solomon et al. (1943) found that 14 out of 40 cases of migraine examined in the U.S. Navy gave abnormal E.E.G., but they did not specify the abnormality.

These findings are chiefly concerned with single records made on subjects at times not specifically related to the migraine, and they suggest little of diagnostic value. However, Engel et al. (1944) found that in decompression sickness (caisson disease) visual scotomata sometimes preceded a unilateral headache. In these cases a focal E.E.G. abnormality in the occipital cortex was found only during the period of scotoma and early headache.

Following this up, Engel et al. (1945) made observations on 3 subjects with clinical migraine in whom an aura of homonymous hemianopia was followed by contralateral hemicrania. They found a similar transient focus of slow-wave abnormality in the occipital region. This happened only when the hemianopia was present, and the record was normal both during the headache and between attacks.

This suggests that the value of the E.E.G. in the investigation of migraine may be increased if repeated records are taken during various phases of the attack. It is also interesting in view of the widely accepted theory of the vasomotor origin of migraine, according to which a prodromal vasoconstriction of cerebral arteries causes such phenomena as defects in the visual field, dysphasia, and other local motor or sensory abnormalities; and a subsequent excessive vasodilatation causes the actual headache (Schumacher and Wolff 1941).

This view is supported by the therapeutic effect of vasoconstrictor drugs (O'Sullivan 1936). It seems likely that a vasoconstriction causing sufficient cerebral dysfunction to produce focal neurological signs would change the electrical activity of the cortex, whereas a simple vascular distension would be less likely to do The results of Engel et al. (1944, 1945) suggest that is the case. The observations cited, however, appe to be inconclusive, and suggested to us that furth investigation might be profitable.

SELECTION OF CASES

The term "migraine" is sometimes extended to co almost any recurrent headache or conditions w subsequent history may establish a progressive struct lesion as the basis of the symptoms. For this we have limited our inquiry to 51 cases of recu headache beginning before the age of 25, sho no irreversible neurological change over a pe of 3 years, and having also at least 3 of the follo 5 features:

(1) *A family history of similar benign headache.*

(2) A pre-headache phase (aura) of transient visual change, dysphasia, paræsthesiæ or weakness of monople hemiplegic distribution, or "psychic" changes of a ste typed pattern for any given case.

(3) Hemicranial distribution at some stage in its cour

(4) Amelioration by vasoconstrictor drugs or by mech occlusion of the common carotid or its branches.

(5) Association with nausea or vomiting.

TABLE I—TRANSIENT ABNORMALITIES OF E.E.G. IN MIGRAIN SUBJECTS

Case no.	Resting record	Record during aura or headache
1	Bifrontal 8 c.p.s. episodes	More conspicuous 8 c.p. episodes
2	Bifrontal 6–8 c.p.s. episodes	Exaggerated
3	Bilateral 8 c.p.s. episodes	Exaggerated
4	Inconstant asymmetrical record	No change
6	Normal record at 12 c.p.s.	Generalised 10 c.p.s. wav
8	Bifrontal 5–6 c.p.s. episodes	Exaggerated
10	Generalised dysrhythmia	No change
11	Generalised dysrhythmia	Exaggerated
12	Normal record	No change
13	Normal record	No change

This arbitrary limitation is designed especially t exclude cases of progressive intracranial disease wit "migraine" as an early symptom. Nevertheless, i view of the vasomotor background of migraine, som cases of vascular malformation or intracranial neopla may be included, for they may cause a sequence o vasoconstriction and overdilatation; just as the may for years show, as their only manifestation, epilepti attacks which are regarded as idiopathic (Penfield an Evans 1935).

AIMS AND METHOD

Information was sought on three points: (1) th incidence of generalised persistent dysrhythmia, of th type seen in epileptic stock, compared with that in th normal population; (2) the possibility of discovering transient focal abnormality during the aura of an attack and of correlating its localisation with the symptoms o signs; and (3) the possibility of discovering a persisten focal abnormality, which would suggest that the migrain was only a symptom of progressive intracranial diseas and might aid its early diagnosis.

A Grass E.E.G. machine was used with a 3-channe ink recording system. Three routine positions wer used in all cases: right and left frontal, parietal, an occipital leads, and transverse temporoparietal lead In cases where these records indicated it, further lead relation to any focus of abnormality, were used. al leads were also used in searching for focal lity in relation to the aura of an attack. Criteria rmality were those agreed to by the Electro-alographic Society (Williams 1941).

FINDINGS

e of Persistent Dysrhythmia

e 51 cases (aged 14–56), 30 had persistently al records. This is significantly higher than the ed 10–15% of abnormality found in a normal ation—i.e., those with no personal or family history igraine, epilepsy, or other neurological disease is 1942, Gibbs et al. 1942, Hill and Watterson 1942). ese 30, 14 had generalised non-specific dysrhythmia, ad bilateral symmetrical episodic activity at 6–10 es per sec. (c.p.s.), and 4 had localised unilateral abnormality. These were all present in repeated records taken between attacks. No less than 21 of the 30 had a positive family history of migraine.

Records were also taken of 36 relations, aged 11–57, of the migrainous subjects. Generalised dysrhythmia was found in 15. But of these, 6 had a history of migraine or of epilepsy. Excluding these, the incidence of dysrhythmia was still 9 out of 27 subjects with no personal history of migraine or epilepsy, compared with an expected incidence of 4 out of 27 normal subjects.

Transient Abnormality

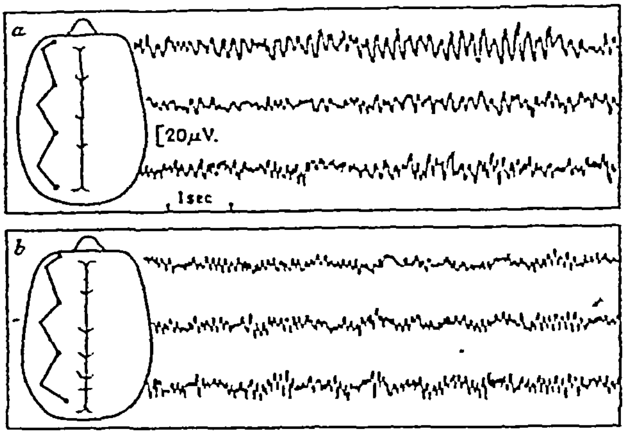
Records were obtained in 13 cases during an attack: in 10 during the aura or at the onset of headache, and in 8 when the headache was fully developed. The findings in the first group are summarised in table I.

The accompanying figure shows the E.E.G. records during the aura and during the headache in case 8. The increase of 5–6 c.p.s. waves is well shown.

The case was that of a male student, aged 22, who had had recurrent headaches since the age of 11 years. These were left frontotemporal in distribution, always associated with nausea and usually with vomiting. Since the age of 15, and possibly earlier, they were preceded by an aura. He would wake in the morning feeling extremely cheerful and on top of the world. This would be reflected also in his behaviour, which would be unusually boisterous and uninhibited. About 11 A.M. his headache would start and gradually increase in intensity, and in 2 or 3 hours he would feel so wretched that he would, if possible, retire to bed. Nausea and vomiting came on at this stage.

Ergotamine taken early in the headache would abort the attack. When he had learnt to recognise the aura, the drug taken late in this would usually, but not always, prevent the attack.

There were no abnormal physical signs and his past health was otherwise good. His father had migraine and asthma.



Electro-encephalographic record of case 8: (a) at aura stage with onset of slight headache; (b) during severe headache.

TABLE II—RELATION OF TYPE OF AURA TO TYPE OF E.E.G. ABNORMALITY

Case no.	Type of aura	E.E.G. between attacks	E.E.G. during aura or early headache
1	Right homonymous hemianopia	Bifrontal 8 c.p.s. episodes	Exaggerated
4	Teichopsia	Variable generalised asymmetry	No change
5	Left homonymous hemianopia	Generalised dysrhythmia	No change
6	Left homonymous hemianopia	Normal record, 12 c.p.s. waves	Generalised 10 c.p.s. waves
7	Scotoma or hemianopia	Normal record	Not done
11	Teichopsia	Generalised dysrhythmia	Exaggerated 6 c.p.s. activity
2	"Feels queer and off colour"	Bifrontal 6–8 c.p.s. episodes	Exaggerated
8	Euphoria and elation	Bifrontal 5–6 c.p.s. episodes	Exaggerated

In the 8 cases in which the E.E.G. was made during the headache the records were indistinguishable from resting records.

In 8 of the 13 cases an aura preceded their attacks. The relation between type of aura and E.E.G. abnormality both between and during attacks is shown in table II.

None of the 6 cases with visual aura showed focal abnormality either during the aura or between attacks; 2 cases with a "psychic" aura showed an exaggeration of a frontal episodic abnormality. It is tempting to link the locality of the abnormality with the type of aura; but this is unjustified, because the same localisation of abnormal waves was found in a case with a visual aura.

Persistent Focal Abnormality

In 4 cases there was a persistent focal abnormality: 1 in the right frontal, 1 in the left parietal, and 2 in the left occipitoparietal regions. All 4 showed transient focal neurological signs associated with their headaches. Ventriculography, done in 3 of these, revealed no abnormality. All 4 showed no sign of a progressive lesion at follow-up 2 or 3 years after first being seen and 7–33 years since the onset of their symptoms.

DISCUSSION

The incidence of generalised dysrhythmia is high in the E.E.G. records both of migrainous subjects and of their relations. This fact confirms the considerable evidence for the constitutional basis of migraine.

A transient focal abnormality during the aura, as observed by Engel et al. (1945), was not found in the present cases, but exaggeration of a previous abnormality was seen in some cases at the time of the aura. The changes noted by Engel et al. disappeared rapidly when the visual symptoms cleared. The fact that our records of cases with visual aura were taken when this was receding may explain the difference.

The exaggeration of a previous abnormality is compatible with a vascular basis for migraine, and is in keeping with the observations of Darrow and Graf (1945) that abnormal high-voltage activity can be induced in the cortex of cats by producing cerebral vasoconstriction.

Further support for this theory was afforded by our observations on the E.E.G. changes following the injection of ergotamine tartrate. In 5 cases intravenous ergotamine tartrate 0·5 mg. was given, and records were obtained before and within 5 min. of the injection. In 2 cases the resting records were normal, and there was no change after the ergotamine. In 3 cases general or local abnormality was shown by the resting records, and in all of these the dysrhythmia was increased by ergotamine. In 1 case with localised dysrhythmia a gradual increase in amplitude was seen, with spread of the abnormality to the opposite cortex, with the result that large 6 c.p.s. waves were present bilaterally. In the first 2 cases the headache was not relieved by ergotamine, whereas in the last 3 it was.

These results suggest that a series of readings made throughout the whole migraine cycle is desirable, but the crucial period is that of the aura rather than the headache.

Persistent focal abnormality does not appear to be of much diagnostic value in these cases. Such a finding at a site corresponding to the neurological manifestations of an attack does not necessarily indicate a focus of progressive intracranial disease.

Conversely, where migraine may be a symptom of organic brain disease, normal records can give a false sense of security.

In one case, not in the present series, a patient with migraine of many years' standing began to develop persistent neurological signs between attacks. An E.E.G. taken at this time showed only a generalised cortical dysrhythmia. Some three months later he was admitted to hospital, as his signs appeared to be progressing. The E.E.G. now showed a focus of increased abnormality in the right temporal region, and at operation an astrocytoma was found in the frontotemporal field.

Nevertheless, the routine use of the E.E.G. in investigating these cases is always advisable, for a small focal lesion may be clearly demonstrated in some instances.

It therefore appears worth while to make E.E.G. studies in all cases of migraine, for accumulation of such records will help us to understand constitutional dysrhythmias. If correctly timed, they may also help to correlate clinical findings with cerebral localisation.

SUMMARY

Of 51 cases of migraine studied by electro-encephalography abnormalities were found in 30: generalised dysrhythmia in 14; symmetrical bilateral episodic activity in 12; and a persistent focal abnormality in 4.

Exaggeration of a previous abnormality was noted only at the period of aura or early headache in 5 of 8 cases, and after ergotamine tartrate in 3 of 5 cases.

The transient focal abnormality found by Engel et al. (1945) was not observed.

The value of E.E.G.'s in migraine is discussed, and it is emphasised that the time in the migraine cycle at which records are taken is important.

TECHNIQUE OF LARYNGEAL ANÆSTHES

R. R. MACINTOSH
D.M. Oxfd, F.R.C.S.E., D.A.
NUFFIELD PROFESSOR OF ANÆSTHETICS IN THE UNIVERSI
OF OXFORD

ANÆSTHETISING the larynx with cocaine or one of substitutes is, or should be, an integral part of laryn intubation and of bronchoscopy.

The usual ways of doing this are all open to s criticism. The difficulty lies in depositing the solu where it is required—on the inaccessible larynx trachea. One technique accomplishes this by bo squirting 2 or 3 c.cm. from a syringe through the mo on to the posterior pharyngeal wall; after which anæsthetist side-steps smartly out of the line of patient's mouth and relies on the violent gagging coughing to spread the liquid throughout the phar and larynx. On the whole the procedure works, bu is unpleasant and unsightly.

With *the type of spray in common use the liqu* atomised almost entirely in the form of large dropl This would be of little importance were it not for fact that the pathway from the nozzle to the lar is not a direct line. The trouble, in practice, is that larger and therefore heavier droplets continue in the in which they are propelled from the spray, and adl to any structure on which they impinge. Thus greater part of the solution is deposited on ton posterior pharyngeal wall, and turbinates, and only very light droplets are carried by the air current thro the irregular upper respiratory passages to the lary only a small proportion of the atomised liquid there is effective.

With the advice and technical help of Dr. H. Epstein I set out to find an easy means of anæstheti the air passages, particularly the larynx. Firs Collison's inhaler was tried. Solutions of cocaine to 50% were placed in the glass bulb and nebulised passing 8 litres of oxygen a minute through it. "fog" was delivered through the standard face-p to a patient under light general anæsthesia. E after 5 min. only 0·25 c.cm. was nebulised. There no evidence of the larynx being anæsthetised. particles from such an inhaler are so small that onl minute fraction are deposited en route; practically pass into the bronchial tree, just as they do when penic solutions are used in the inhaler.

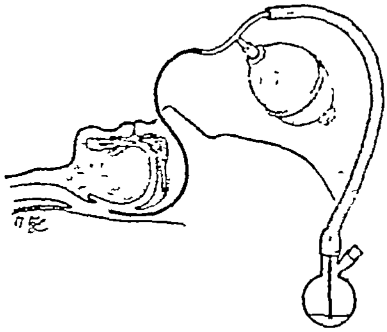
Later the Drager, 'Rybar,' and 'Deedon' inha were tried, but the same situation was encounter large droplets adhered to the many structures met before the larynx was reached, while the very s droplets were carried deep into the bronchial tree. larynx became anæsthetised eventually, but at expense of as much solution as when the more sin sprays are used.

A small experiment shows that the large droplets f a spray adhere on impact, and explains why a spray f one of the common devices, through the nose or mo is inefficient in anæsthetising the larynx. Hold a rul tube straight and blow a spray into one end; the sp comes out of the other end practically unchanged. curve the tube slightly, and repeat the experim Only a small proportion of the solution, in the form finer droplets, comes through as a spray; larger drop condense in the tube, and liquid dribbles out of the di end. The more the tube is curved the greater the fil ing action it exerts. In clinical practice it is true t if the bulb is squeezed on inspiration, some medi sized droplets are carried to the larynx, but these f only a small part of the total volume of liq atomised.

o far as I can trace, the first to attempt to overcome se difficulties was Rowbotham (1945). In 1937 he made ng, curved, fine, but rigid metal spray, designed so t when introduced through the nose of the unconscious ient the tip of the nozzle could be directed at the ynx. Used with understanding the spray is strikingly cessful in a large proportion of cases, but perhaps s qualification is enough to prevent its widespread ption.

In 1945 Harang described a method which involved patient's cooperation and, at the same time, is bject to some of the other disadvantages I have scribed.

In 1945 Kenton made a big advance by describing long malleable tube through the distal end of which spray could be made to issue. The technique he scribes gives excellent results, but in our hands is casionally disappointing. Kenton advocates that, ter light general anæsthesia has been induced, a nasoharyngeal airway—i.e., shortened endotracheal tube—ould be passed through the nose. He then introduces is specially designed tube through this outer tube and rays the larynx from close quarters. We found that e outer tube occasionally caused nasal bleeding; and, the nares were narrow, the outer tube became firmly ipped, making it difficult to control the direction in hich the tip pointed. Unless care is taken to hold the glass container low, the solution quickly siphons from it into the pharynx. Moreover, the technique is hardly suitable for a conscious patient on whom, for example, a bronchoscopy is to be done.



The soft rubber tube of the atomiser I use is identical with Magill's endotracheal tube for infants, size 00, with a nozzle on the end. It is passed directly and easily through the nares. After passing the soft palate the tip is directed by the natural curve of the tube towards the glottis, which can thus be sprayed readily. When this has been done an endotracheal tube can be passed readily through nose or mouth either blindly or by direct vision. To prevent siphoning, the glass container of the spray hangs lower than the nozzle; and, since the glass container always hangs downwards, the spray can be held in any position.

Technique.—I use a weaker solution of cocaine than that generally advocated. Analgesia from a 3–4% solution is slightly slower in onset and shorter in duration than from the 10–20% solutions commonly used, but otherwise is equally effective. 1 c.cm. of 10% cocaine is placed in the container, and 2 c.cm. of tap water is added. I usually use the lot—100 mg. of cocaine hydrochloride. If the patient is to remain conscious, the nose is sprayed and the nozzle advanced as the mucosa becomes insensitive. More commonly the patient is given 'Pentothal' and the lubricated tube is passed about 5 in. through the nose. The bulb is compressed, and a fine spray spreads over the larynx and pharynx. The position of the nozzle is varied by pushing in or pulling out the tube slightly. A cough or interruption of the patient's regular breathing is a sure sign that the spray has found its target. After 2 min. analgesia is perfect.

If bronchoscopy is to be performed, the nozzle is directed through the cocainised larynx well down into the trachea. The bulb is squeezed on inspiration to ensure that the inspiratory air stream carries the spray at least as far as the carina.

Using this technique, members of this department have sprayed themselves and passed endotracheal tubes blindly on themselves without any difficulty.

I am indebted to Mr. H. G. Epstein, PH.D., and Mr. R. Salt, who, over a long period, have made up for me various models until the present one was evolved.

The spray can be obtained from the Longworth Scientific Instrument Co. Ltd., of Longworth Road, Oxford.

Preliminary Communication

AN EARLY SIGN IN SPRUE

THE SPLIT : UNSPLIT FAT RATIO IN THE FÆCES

DURING 1944 thirty-six cases of sprue syndrome were collected at Karachi. Thirty were early cases, eighteen of these developing at Karachi within three months of their arrival in India, and the remaining six were chronic cases evacuated from Iraq. Any sign which would help to distinguish sprue from the other numerous forms of bowel disease was very welcome, and such a sign was found in the alteration of the ratio between the split and unsplit fat in the fæces.

As happens in early cases of sprue, the total percentage of fæcal fat was often within normal limits, but at this stage a significant rise in the split : unsplit fat ratio could usually be demonstrated, particularly if the patient was put on a fat-free diet.

Of eleven cases on a full diet of 110 g. of fat daily, four had a total fæcal fat below 35%, but in only one was the split : unsplit fat ratio also within normal limits. In eighteen others, tested on a low-fat diet containing 16 g. of fat daily, for which the normal was a total fæcal fat of up to 20% with a split : unsplit ratio of 3 : 1, there were ten with total fæcal fats below 20%, and of these only two had a normal ratio; in the remaining eight, with fæcal fat above 20%, the ratio was greatly increased in every instance. Thus the ratio was found to be increased in eleven of the fourteen doubtful cases.

The milder cases responded to treatment with 150 mg. of nicotinic acid daily and a low-fat diet of 16 g. of fat; in chronic cases liver therapy was also introduced. During recovery, the total fæcal fat often returned to within normal limits quite rapidly, but the fats ratio lagged behind by one or two months. This lag was a useful indication of incomplete recovery; the two relapses which occurred heralded their arrival by an increase in an already raised split : unsplit fat ratio, the total fats being normal. A temporary rise also was often noticed when a convalescent patient was changed from a low-fat to a full diet, giving warning that recovery was not absolute.

It is not suggested that a raised split : unsplit fat ratio is an infallible test for sprue, but that it is a helpful sign in early or doubtful cases. Since there is a lag in the return of this ratio to normal, it can be used to determine the end-point of the episode.

Ashford County Hospital,
Middlesex.

Reviews of Books

Medical Disorders of the Locomotor System

Ernest Fletcher, m.d. Camb., m.r.c.p., physician to the arthritis clinic and lecturer on rheumatic diseases, Royal Free Hospital, London. Edinburgh: E. & S. Livingstone. 1947. Pp. 625. 45s.

The practice of a clinical specialty must be justified in the first instance by the benefit to the patient of professional advice based on a more extensive knowledge and experience of a particular disease or group of diseases than can be offered by the general practitioner. The specialties which are likely to endure have grown slowly and naturally out of general medicine and surgery, and it is incumbent on those who practise them to seize the many opportunities which come their way for the scientific study of the diseases they treat, and not to be content merely with the routine application of some complicated but empirical therapeutic procedure.

Orthopædic surgery has long been accepted as a legitimate specialty. In this book Dr. Fletcher and his collaborators show that the anatomy, physiology, and pathology of the locomotor system can make a satisfactory basis for specialised medical as well as surgical practice. They seek to include in this field much more than what are commonly termed the rheumatic diseases, and in their approach to it combine to maintain the broader outlook of the general physician rather than the narrower view of the specialist in physical medicine. They advocate in fact orthopædic medicine as a specialty comparable with orthopædic surgery.

Following the opening chapters on clinical examination and joint pathology there is a well-illustrated account of the applied anatomy of the locomotor system by Prof. G. A. G. Mitchell. In a special chapter on the incidence and prevalence of adult rheumatism, Mr. E. Lewis-Faning, ph.d., shows how inadequate are the existing morbidity data and how difficult it will be to improve them. The relation of focal infection to locomotor disorders, and the assistance which can be offered by the pathologist and the radiologist in their diagnosis, are dealt with at some length by special contributors. Dr. Fletcher uses with advantage a practical clinical approach in his chapters on arthritis, sciatica, and the various cervicobrachial syndromes. Dr. W. S. C. Copeman contributes a useful section on fibrositis, and Dr. Donald Hunter a short but comprehensive account of the medical diseases of bone. The book concludes with a short chapter on physical therapy.

It seems likely that the chronic rheumatic diseases will have more attention under the new health service, and physicians intending to specialise in this field will find in this symposium a comprehensive review of current theory and practice as well as an extensive bibliography which will suggest further reading.

Municipal Health Services

Norman Wilson, m.a., d.p.a., lecturer in public administration, University of Liverpool. London: Allen & Unwin. 1947. Pp. 178. 7s. 6d.

Mr. Wilson has had many years' practical experience of the work of health departments, the results of which are obvious throughout this volume. Although it was written before precise details of the National Health Service Act were available, its essential value is not affected and it will be invaluable to social workers, members of local authorities and regional hospital boards, and a wide circle of medical readers interested in the administrative aspects of the new service. Existing services, and the powers on which they are based, with particular reference to those of the all-purpose authority, are described with clarity. The provision of poor-law medical services and of school medical services by separate committees leads to a thoughtful disquisition on integration, incidentally apposite to the new structure. The duties of the m.o.h. and his numerous specialist medical colleagues, the functions of the Ministry of Health, the advantages and disadvantages of joint boards, and the need for large health units with sufficient financial resources are well handled.

Ancient Anodynes

E. S. Ellis, m.r.c.s. London: W. Heinemann. 1[illegible] Pp. 187. 21s.

Dr. Ellis's survey of the history of all forms of [illegible]thesia from primitive up to recent times has evide[illegible] been a labour of love. He has avoided the dange[illegible] writing an encyclopædia of names and dates, and [illegible] enriched his account with many apposite quotati[illegible] professional and lay. Man from his earliest days [illegible] sought to escape pain, and roughly speaking the anod[illegible] devised fall into two classes—those which stimulate [illegible] excite, and those producing anæsthesia. To these [illegible] be added anæsthesia resulting from hypnosis, [illegible] similar psychological methods. Dr. Ellis reviews [illegible] all, with plenty of telling incidents. He might per[illegible] have given fuller details of the use of anæsthesi[illegible] ancient Greece, scene of the first civilisation in Euro[illegible]

Dynamic Aspects of Biochemistry

Ernest Baldwin, b.a., ph.d., university lectur[illegible] biochemistry, Cambridge. London: Cambridge Un[illegible]sity Press. 1947. Pp. 457. 21s.

Biochemistry is concerned with (1) the nature of the constituents of living matter, and (2) the chemical reactions which take place therein. Confining himself to the latter, Dr. Baldwin has written a book which was badly needed and will be widely welcomed by students, teachers, research-workers, and those who wish to keep in touch with modern conceptions of metabolic processes. Developing the book from his biochemistry lectures for part I of the natural sciences tripos at Cambridge, he begins with a systematic survey of enzymes, and goes on to treat metabolism from the viewpoint of enzyme biochemistry. The time is indeed ripe for such an essay; the present understanding of the fermentation process and of the tricarboxylic acid cycle of carbohydrate oxidation, the new concept of the energy-rich phosphate bond, and the new knowledge won by the use of isotopes *make it possible to tell a coherent story of the* processes of carbohydrate, fat, and protein metabolism and their interrelations. The many tables, the novel method of depicting enzyme reaction sequences by what the author calls "whirligigs," and the unusually good index add to the quality of the book.

Psychiatric Interviews with Children

Editor: Helen Leland Witmer. New York: The Commonwealth Fund. London: Oxford University Press. *1946. Pp. 443. 25s. 6d.*

Here is a good idea. Everybody would like to know, and the beginner in psychotherapy needs to know, what goes on between the expert and his patient. As it is difficult, if not impossible, to listen in, the next best thing is to read what the psychiatrist said, with explanations, such as these authors kindly provide, of why he said it. The trouble about this book is that it makes it all seem much too easy. The patients shed their problems after a little conversation which, but for the footnotes, might be thought to be casual. That so brief a form of therapy should be successful suggests that the methods of selection and the type of case are not the same in the United States as here. The impression is that the cases were less severe than those considered to be "treatment cases" in our clinics. We need not doubt that the simple case responds to simple methods, nor question the wisdom of providing services so lavish that simple cases can receive attention; but a second volume would be welcome to let us into the secrets of treatment of the long, intricate, and "sticky" case.

Textbook of Surgical Treatment (3rd ed. Edinburgh: *E. & S. Livingstone. 1947. Pp. 644. 32s. 6d.).*—Prof. C. F. W. Illingworth and his 21 collaborators have brought this well-known and well-balanced textbook up to date. The chapter on wounds and their infections has been rewritten, and there are new sections on penicillin in surgery, faciomaxillary injuries, plastic surgery, and reablement. Among new *material scattered through the text are accounts of the* Rh factor, the use of protein in surgery, and the anticoagulant treatment of thrombosis. Some 60 new illustrations have been added.

SURFACE ANAESTHESIA

with

NUPERCAINE

"Fortunately, Nupercaine is a complete substitute for cocaine."
Practitioner, 1936, 136, 509.

NUPERCAINE LOZENGES

each containing 1 mg., produce a prolonged anaesthesia of the mucous membranes of the mouth and throat, alleviate the discomfort of sore throat and allay post-tonsillectomy distress. *(Boxes of 15 and bottles of 100)*

NUPERCAINAL

a 1 per cent. ointment producing prolonged analgesia in chaps, herpes zoster, burns, sunburn, anal fissure, haemorrhoids, pruritus. *(Tubes of 1 oz.)*

NUPERCAINE SUPPOSITORIES

each containing 0.012 g., may be employed in the treatment of anal fissure and painful haemorrhoids or, post-operatively where a prolonged action is desired. *(Boxes of 5)*

NUPERCAINE 2% SOLUTION

for anaesthesia of the mucous membranes of the ear, mouth, throat and nose. May be employed topically in proctology. *(Bottles of 30 c.cm.)*

NUPERCAINE LUBRICANT

an efficient anaesthetic lubricant containing 10%, for use with tracheal tubes only, facilitates introduction and renders their presence more tolerable. *(Containers of 1 oz.)*

Samples are available for clinical trial.

* A copy of The Nupercaine Handbook, Part II, Ciba Handbook No 2. second edition, a 32 page survey of the special advantages of Nupercaine for surface, infiltration and regional anaesthesia, will be sent free to members of the Medical Profession on request.

MERSALYL B.D.H.

The Standard Mercurial Diuretic

The use of Mersalyl B.D.H. is indicated for the relief of acute œdematous conditions if it is reasonably certain that there is no severe renal impairment and when the administration of a diuretic over prolonged periods is necessary. When cardiac action is impaired premedication with digitalis may be advisable.

Mersalyl B.D.H. is usually given intravenously, but it may also be given intramuscularly. In less severe cases treatment may consist of one injection in order to induce diuresis which may be prolonged by giving tablets of Mersalyl B.D.H. orally or suppositories of Mersalyl B.D.H. rectally.

Mersalyl B.D.H. conforms with the specification for Mersalyl B.P. and is issued in solution (Injection of Mersalyl B.P.) in ampoules, in tablets (0.08 grm.) for oral administration and in suppositories (0.4 grm.) for rectal use.

Details of dosage and other relevant information on request

pH

ACID MILKS IN INFANT FEEDING

BEURLAC

A buttermilk in powder form, useful for infants suffering from gastric disorders.

PROLAC

Of approximate half cream fat standard, but with increased protein, as required in gastro enteritis.

LACIDAC

SEPARATED

Almost fat free. Invaluable in cases of fat intolerance.

HALF CREAM

An intermediate grade for less severe cases and for graduation to normal feeding.

FULL CREAM

Suitable for long term use, or as a final stage of graduation to normal feeding.

The wealth of buffer substances in milk results in the absorption of considerable quantities of acid in the digestive tract. In certain cases it is reasonable to give the infant the kind of nourishment which necessitates the least effort, and controlled acidification offers a means of reducing demands on the secretory functions. In view of the varied nutritional needs of infants requiring acid milk, the following range of products is available :—

★ *Particulars of these and other Cow & Gate preparations for specialised infant feeding, will be gladly forwarded on request.*

THE LANCET

LONDON: SATURDAY, JULY 12, 1947

Boards and Management Committees

THE appointment of the regional hospital boards ings us face to face with some of the implications the National Health Service. The interval since the iscussions in Parliament has revealed a pretty general nsensus of opinion that the hospital part of the ct is on the whole well designed, and that it is at ast much better than the alternative proposals of e Coalition Government. The fiction so long throned at Whitehall that local-government machin-y alone provided the means by which a health rvice could be run is now happily dead, and it is sy to detect a widespread relief strongly tinged with al optimism for the future.

A year ago attention was concentrated on the need r three things—good regional machinery, sufficient dependence for the hospitals and their management ommittees, and a financial system which would avoid he strangling effects of Treasury control. To take he last point first, there is now solid ground for elieving that the need for global budgets rather than temised control is fully appreciated by the Ministry f Health, and that it has been or will shortly be ccepted by the Treasury. The future alone can show ow far the method can be carried in practice. The mendments made in Parliament enabling hospitals o accept funds from other sources will be a significant afeguard. A double system whereby the main urden falls upon the Exchequer and oppor-unity is yet left for voluntary effort to play its art promises to preserve the best traditions of the ast.

What of the regional boards and the hospital anagement committees ? Many have been wondering ately whether the boards can carry the loads assigned hem. More mature consideration than was possible last year suggests that the task imposed on the individual who accepts membership may prove so exacting as to deter the capable and energetic man or woman with numerous other interests. Frequent meetings at regional headquarters which may be far from home ; many subcommittees, even if full use is made of coöpted personnel ; a heavy dose of agenda papers and reports to be absorbed—may not this burden prove too much on a purely voluntary unpaid basis ? May it not lead to congestion and delay, and throw too much upon the officials ? This is certainly one of the major sources of anxiety. Another touches the hospital management committees. Granted a reasonable measure of independence, will the larger units of the future enlist the same degree of local interest and enthusiasm as the units of today ? Will it in fact be possible—and the answer can only be guessed by thinking of individual cases—to secure in a group of hospitals a sense of pride and ownership equal to that which now surrounds almost every voluntary hospital ? These are genuine anxieties which ought not to be dismissed as indicating a premature defeatism ; and two or three suggestions may be offered.

In the first place, it is well to remember that the conception of the regional board is founded upon the experience of voluntary bodies of an advisory rather than an executive character. It was the experience of the regional councils sponsored by the Nuffield Trust, and the analogy of bodies such as the King's Fund in the metropolitan area, that furnished the background upon which the Ministry worked in drafting the Act. Once the decision to accept the regional principle and to give the boards executive functions had been taken, the question arose whether to proceed by way of voluntary bodies on the Nuffield model or by way of whole-time or part-time paid personnel—" commissioners " as they were called in one of the earlier tentative reports. The latter would have been small, mainly expert, bodies composed of men of the type who prepared the surveys. Such men would have had time to make themselves masters of their subject, and to know their regions from A to Z. The fact that the Ministry chose the former alternative is not surprising, nor need it be a ground for criticism ; but it was perhaps a pity that a decision had to be taken before the full implications could be seen. What now seems important is that some compromise with the latter principle of expert personnel on a paid basis should not be ruled out of account simply because it is not suggested in the Act. If it appears, in say six months' time, that the regional boards as now constituted are snowed under by the mass of work falling on them and on their executive staff, can the Minister still perhaps come to their rescue by appointing on a paid basis but as full responsible members of the boards a few of the survey officers and others equally well fitted to provide a hard core of strong personnel in the region ? The possibility should be kept in mind even if legislation were required, for it begins to look already as if something of the kind might make just the difference between success and failure.

Secondly, there is the anxiety noted above about the size of the units to be controlled by the hospital management committees. It is true that no rigid rule as regards size is laid down in the Act, but it is generally expected that the regional boards will follow broadly the indications in the surveys which point to something like a thousand beds as the average unit. Such a unit, it has been repeatedly argued, is necessary if the full range of service is to be provided. Here surely it is advisable to pause and remind ourselves that at the time the surveys were carried out the regional conception existed only in embryo : may it not be that much of the coördination of development of hospitals, of medical staff, and of inter-hospital services could now equally well be achieved through regional control in these matters ? The conception of grouping into thousand-bed units represents an earlier approach to the problem of coördination, and the more recent regional idea has been superimposed on it—with the result that the machinery for coördination is in danger of becoming top-heavy. Given regional control on the points that matter, it should be possible to approach the problem with a much more open mind, and to allow more weight to the need to keep the function of management essentially local. Service on the management committee of the hospital in one's own town or immediate district is quite a different thing from service on the management committee which meets at the larger hospital ten miles away. There are innumerable instances, where the grouping of several hospitals under one management is foreshadowed in the surveys, which could with advantage be reviewed from this angle. Regional control makes it reasonable to allow more latitude in granting management-committee status than could possibly have commended itself to the surveyors three or four years ago in the absence of an alternative means of achieving coördination. Some official recognition of this fact by way of guidance to the regional boards would go far to allay widely prevalent disquiet.

There is another thing which we can see more clearly now than was possible a year ago. In their desire to secure a proper chain of authority from the Minister downwards, the draftsmen of the Act provided that the regional boards should be appointed by the Minister, and the hospital management committees by the regional boards. This is intelligible and logical. It may be workable at regional level; but when it comes to the hospital management committees it is going to be very difficult to choose the right people. Lacking, as they often must, intimate personal knowledge of the people concerned, the regional boards will be guided partly by paper qualifications and partly by hearsay or recommendations which come in from other bodies. Someone says that so-and-so would be a good member; it sounds probable; so we will appoint him or her. Is this method going to work as well as the older method of the voluntary hospitals, which has usually amounted in practice to a form of coöption? The older method is open to criticism and to occasional abuse, but in the main it has worked pretty well. Its chief weakness is a tendency for people to hang on to office too long—a weakness which the regional board can well control. The method of appointment from above is equally open to criticism and to occasional abuse, and on the whole committees appointed on these lines have certainly not shown themselves decisively superior; in fact they have often failed to develop a corporate personality. Is not some compromise needed to make the best of both worlds? Let the regional boards name a nucleus for each hospital management committee, but having done so let them *trust those they* have chosen and leave them to submit the names of the rest of the committee. In this way a real team can be built up, and the regional board can at the same time assure itself of control amply sufficient to safeguard the chain of responsibility required by the structure of the Act.

The Act must after all be regarded as a compromise between the principle of ministerial responsibility on the one hand and reliance upon voluntary service on the other. Having discarded reliance on local-government machinery, the Act relies on the element of voluntary service to supply the energy and initiative without which the whole machine will tend to run down. It is not too much to ask that at the point where this initiative is most essential—at the management-committee level—the principle of ministerial responsibility should yield a little ground. The old idea of coöption has in this country a good ancestry by no means confined to the voluntary hospitals of the last 200 years; it holds good in varying degrees for universities and schools and city companies, and voluntary allegiance to a unit which does not possess this privilege of adding to its own numbers comes near to being a contradiction in terms. It would be well, therefore, not to press too hard here the power of appointment vested in the regional board, and to recognise that in practice whenever there is no strong case to the contrary the choice of its personnel should rest with the hospital management committee itself.

Filthy Rivers

THE progressive pollution of *our rivers is* an evil which Parliament will have a chance to check when the Rivers Boards Bill, embodying the recommendations of the Central Advisory Water Committee, is at last introduced. The Rivers Pollution Prevention Act of 1876 largely failed of its purpose because the Minister of Health, the authority who decides what constitutes pollution, must be satisfied that there are practicable means of rendering an effluent harmless and that these means will not inflict material injury upon the industry concerned. Section 8 of the Salmon and Freshwater Fisheries Act of 1923 authorises proceedings against any person who knowingly permits to be discharged into waters containing fish any matter to such an extent as to be injurious to fish or to the food of fish. The proceedings can be taken by a fishery board or by any person who obtains a certificate from the Ministry of Agriculture and Fisheries stating that he has a material interest in the affected waters. But fishery boards have not been rich enough to afford costly legal proceedings. Moreover, where there is pollution from several sources—as, for instance, at Tynemouth—it is scarcely possible to prove that injury to fish is due to any one pollution. At Tynemouth, where the entirely untreated sewage of Newcastle and Gateshead and other large towns turns some 30 million gallons of filth into the tidal reaches per day—a mass which cannot get away to sea in a single tide but must move up and down the estuary for several tides before it is cleared—the tidal water is not a "stream" within the meaning of the Act.

Facts of this nature are brought out in a pamphlet entitled "Pollution" which the British Field Sports Society has just published. It contains a study by Mr. H. D. TURING (formerly angling editor of the *Field*) of the condition of the Trent, Tyne, Eden, Ribble, Lune, Wyre, and Severn, and a report by Mr. G. M. KING (of the Dee Fishery Board) upon the Welsh Dee. These statements, in non-technical language, may help to educate the public and the legislature. It is the appalling truth that the treated effluents from sewage and industrial works, when reasonable measures have been taken to prevent pollution, are turned into streams less pure than the ffluents. Even the present inadequate statutory provisions can work good results if only the law is nforced. The industrial revolution of the 19th entury ruined the Ribble. The salmon catch, from ods and nets in the river, was 15,000 fish in 1867. In ten years it dropped to 6000; in 1887 it was 2400; n 1897 it was 528 (sea-trout as well as salmon); in 1914 it was 280. Money paid as compensation under ocal Acts became available about 1930 for taking proceedings for breach of anti-pollution statutes. In 1931 the stock of salmon in the river was estimated 556 fish; in 1941 it had risen to 3263.

The pamphlet is mainly interested to show how ngling has suffered. But the story is not merely ne of oxygen deficiency in rivers. A 1945 report by fishery board on the state of the Lune has some rim hints of poisoned fish sold locally by unauthorised nders. The coast-line from Liverpool to Barrow, erhaps 150 miles in length, receives about 200,000 allons of crude sewage every mile every 24 hours, or bout 40 large buckets full every yard daily. "This," emarked the report, "is the cesspool that thousands f people bathe in during the hot summer months nd this is where our shrimps and prawns live and eed."

Intravenous Iron

When Pierre Blaud compounded his famous pill, 116 years ago, he used equal parts of potassium carbonate and ferrous sulphate, and the recommended dose yielded gr. 6–24 of ferrous carbonate daily. Unfortunately official "improvements" were less effective and the doses recommended were too small, so iron treatment suffered a partial eclipse The modern use of larger doses than were in vogue even 20 years ago has a solid basis of quantitative research. It is known that 5–8 mg. of iron is needed daily to keep a man in iron equilibrium. Leverton and Roberts[1] pointed out that women up to the menopause need twice to four times as much as men, especially during pregnancy when the daily iron requirement is 20 mg. or more. Young children need about 0·6 mg. per kg. body-weight. A recent survey by Bransby and Magee[2] shows that even the post-war British diet provides about 11 mg. of iron a day for adults, which is enough for men but not enough for women. The pre-war diet was probably adequate in iron except during pregnancy, when the intake was very often insufficient. It is not surprising, therefore, that microcytic iron-deficiency anæmia is common in this country.

The figures on which estimates of the amount of iron, and the dosage of iron preparations, required for the treatment of anæmia are based have been summarised by Goodman and Gilman.[3] An adult with 100% hæmoglobin has about 150 g. of circulating hæmoglobin containing 2·5 g. of iron; so that for each 1% hæmoglobin deficiency we must get into the body 25 mg. of iron. Now iron preparations given by mouth are only partially utilised, the proportion depending on the type of preparation and the dose. The best preparations are ferrous salts, about 15% of ferrous sulphate being utilised: the ferric salts are utilised less, and iron in organic combination is hardly utilised at all. The best method of administration is in small divided doses, for raising the individual dose above a certain optimum merely increases the amount excreted in the fæces and so diminishes the proportion utilised. A gramme of anhydrous ferrous sulphate contains 360 mg. of iron, which with 15% utilisation adds about 54 mg. to the circulating iron and so should give a rise of 2% hæmoglobin. Practical experience has shown that no advantage is gained by giving more than 2 g. (gr. 30) of ferrous sulphate daily, and this should produce a hæmoglobin increase of about 4% each day. These figures assume that the rate of utilisation is steady, and that the iron absorbed is quantitatively converted into hæmoglobin. The various workers in England and the U.S.A. who have studied the fate of ingested iron all agree that the amount of iron in the body is regulated by changes in absorption, since there is hardly any excretion of iron once it is absorbed. The amount of iron absorbed from a given dose depends on the state of the body's reserves: if they are depleted, iron is absorbed to make them up: if reserves are adequate, absorption is small. Hahn and colleagues[4] found that in anæmic dogs iron was rapidly absorbed, but in non-anæmic animals absorption was only about 1/70th of that in the anæmic ones. In following the route of the absorbed iron, earlier investigators got irregular results that suggested that a variable though significant proportion of the iron was not converted into hæmoglobin but deposited in the body stores. Recent work with radio-iron has however shown that absorbed iron is almost entirely converted into hæmoglobin within 4 to 7 days after ingestion and very little goes permanently into storage except in the presence of infective disease, when there is increased deposition in liver and spleen.[5]

So, for therapeutic estimates, we are justified in assuming that when we give iron to anæmic patients in optimal doses it will be absorbed according to the percentage utilisation for the particular preparation used and that the iron absorbed will be combined into hæmoglobin. But in patients with iron-deficiency anæmia it is often absorption that is at fault, and even when the anæmia is due to nutritional deficiencies poor absorption of iron may play a part in preventing the expected results being obtained. In some patients with a chronic microcytic anæmia it is very difficult to obtain any response to ingested iron, and it is useless to increase the dose of iron beyond the optimum. The theoretical answer to this problem is to give iron intravenously. Whipple and his co-workers have shown that such iron is almost quantitatively used for forming hæmoglobin. Vannotti,[6] who followed the fate of intravenously injected radio-iron (Fe^{52}) in rabbits, found that it is at first distributed all over the body in the plasma, and a certain amount is excreted by the kidney; during the next 3 days the plasma-iron falls steadily, but only a little iron is transferred to the red cells and most of it finds its way to the liver. The liver gradually releases this iron for combination into hæmoglobin, and from the 10th to the 30th day the amount of radio-iron in the red cells steadily increases, while that in the liver decreases. The iron was shown to be part of the hæmoglobin molecule, and not collected in the stroma of the erythrocytes, by preparing crystalline hæmin that was found to be radio-active. Some of the released iron passes to the bone-marrow, and its passage can be traced by a reappearance of radio-active iron in significant quantities in the plasma. After 30 days radio-iron appears in increased amounts in the bile and can be detected in the spleen; a myoglobin containing radio-iron can also be found; Vannotti considers that these findings are due to hæmolysis of red cells containing radio-iron. Ferrous and ferric irons show somewhat different time-relations in this metabolic sequence up to the 10th day but thereafter it makes no difference what the original dose consisted of. These experiments were done on normal rabbits; in anæmic rabbits the same metabolic sequence occurs, but much more rapidly; iron appears in the liver in a few hours and radio-active hæmoglobin can be detected in 2 to 5 days.

We can thus be sure that iron injected intravenously into an anæmic patient will appear as hæmoglobin in a few days. But attempts to find an iron preparation suitable for parenteral administration have failed because serious toxic effects appeared long before an adequate amount of iron could be given. We have seen that 25 mg. of iron is needed to produce a rise of 1% in hæmoglobin; the maximal dose of the injectio ferri *B.P.* is 6 mg., so this amount would have to be given daily for nearly three months to produce a rise of 20% in hæmoglobin. Recently Goetsch et al.[7] tried injecting infusions of colloidal ferric hydroxide or ferric oxide intravenously; but although as much as 1 g. of iron could be given in this form, all the subjects suffered from unpleasant reactions during the infusion with nausea and sometimes more severe symptoms coming on an hour or two later. In 3 patients the infusion had to be stopped when only small doses (70–180 mg.) had been given. They concluded that the toxic effects were too severe for this method of treatment to be of practical use. In this issue Dr. Nissim claims that saccharated oxide of iron in a relatively concentrated 1% solution can be given rapidly without such toxic effects; as much as 500 mg. of iron in 50 c.cm. was given intravenously in seven minutes; or it could be given by infusion in the more dilute form of a 0·1% solution of saccharated iron oxide in 5% dextrose. Dextrose solution is used to wash any clinging particles of iron oxide away from the venepuncture site. He finds that a dose of 500 mg. of iron produces the expected rise of about 20% in hæmoglobin.

If these findings are confirmed, the problem of treating the patient who will not respond to iron by mouth is solved. A safe intravenous preparation of iron, capable of administration in doses that could be expected to produce an adequate rise of hæmoglobin, has long been needed, and this time success seems to have rewarded the investigator. But iron is so easily given by mouth that recourse to intravenous therapy should still be reserved for the refractory patient.

Annotations

INSURANCE AGAINST STARVATION?

In the Harveian lecture printed at the front of this issue Mr. Walter Elliot delivers some shrewd strokes against Leviathan, which by all the rules should be mortally wounded. At the same time, and in speech in Parliament (p. 73), he joins in the B of the Calories which flared up again after Dr. Franklin Bicknell's assertion that England is dying of starvation.[1] Mr. Elliot's interpretation of the food-consumption figures will please many of his medical colleagues whose personal observations, or personal privations, lead them to reject official assurances that the nutritional state of the nation is as good as before the war. Like other interpretations, however, it is open to criticism, and has the defects of the data it interprets. Calories apart, it seems clear that a proportion of people in this country are not getting enough food to maintain full health, but it remains doubtful whether this proportion is larger or smaller than in 1939. Few would deny that the vigour of the population would be increased—psychologically if not physiologically—if means could be found to give everybody the generous quantities of meat, butter, and eggs formerly enjoyed by the middle and upper classes. On the other hand, our rationing system, with all its imperfections, has safeguarded the nutrition of children and has divided our resources equally enough to make real hunger very rare. We have more food, and distribute it more in accordance with need, than most of our Continental neighbours who offer better fare to visitors. For the present, as the *Economist* puts it, "England is starving to death, if at all, in a strictly Pickwickian sense."

The important question, however, is not so much whether we are starving today as whether we can avoid starving next year, or the year after next, when we cease to live largely on credit. In last week's debate in the Commons Mr. Strachey, as Minister of Food, reflected the optimism on which the Government seem to have lately decided. "I am perfectly sure," he said, "that this country need have no doubt whatever of its ability to obtain an ample food-supply in the coming year". thanks to the effects of drought after an exceptionally hard winter our own harvest prospects are poor[2]; yet no responsible minister could have been so emphatic without good reason. The reason, nevertheless, has not yet been explained; and displays of confidence do not in themselves get over the facts of a situation in which our annual excess of imports over exports is something like £700 million. In such a situation one would suppose that intensive production of food in these islands would be very seriously considered as a form of insurance policy—enabling us to use those immemorial words of comfort "at least we shall not starve." But with their eyes fixed on higher exports, and their feet tied by the difficulties of a wages policy that would induce workers to enter essential industries, the Government have not yet shown any sign of weighing the possible advantages of shifting more of our resources into agriculture; and we believe there should be more public discussion of the arguments again put forward by a correspondent in our Reconstruction column this week. It is true that, in time of scarcity, economy of all resources, both human and material, is very necessary; and obviously there are objections to growing food in Britain which can be bought cheaply abroad. These economic objections would immediately break down, however, if at any time we lacked the money to buy this foreign food. If in circumstances of great difficulty we are prepared to go on spending very heavily on maintaining military services against the risk of war, there is nothing extravagant in the idea that we should

2. See *Times*, July 7, p. 5.

necessary spend some money on maintaining agri-tural services against the risk of starvation—which ·· the whole appears less remote. These islands uire more than one kind of defence.

'or those anxious to see a healthier balance between an and rural life our correspondent's proposals have added interest. They would likewise have appealed, imagine, to Mr. Elliot's centaurs, who had unusual lifications for helping on the farm.

USION OF EDINBURGH MEDICAL SOCIETIES

EW centres outside London are large enough to tain a medical society designed, however modestly, ng the lines of the Royal Society of Medicine, with its arate sections for the various specialties. Last year, wever, a comparable scheme was advanced for nchester[1]; and there is news of a similar movement Edinburgh, where the councils of the Medico-irurgical Society and other local societies are nsidering amalgamation.

Edinburgh has four principal societies: the Royal edical Society, with an undergraduate membership, ich with a history of 210 years is the oldest medical ciety in the country; and three graduate associations the Medico-Chirurgical Society, the Obstetrical ciety, and the Clinical Club. The case for amalgamating e three last has been put by Prof. Edwin Bramwell,[2] o holds that the Medico-Chirurgical Society, in underking by its general constitution to meet the needs of th specialist and general practitioner, satisfies neither. amwell's suggestion is that the society should form edical and surgical sections, but that combined meetings held to discuss subjects of common interest; that the inical Club should be invited to join as a third section d the Obstetrical Society as a fourth. To those who int to the Medical Society of London which, with a nstitution similar to that of the Edinburgh society, ntinues to fulfil an active and useful rôle, he replies ith reason that the London society offers the attractions a centrally situated house, with hall and library; at it draws members from the whole London area; nd that many members are also fellows, and may ttend sectional meetings, of the Royal Society of edicine.

An invigorated society would, as Bramwell says, be n added attraction to postgraduates visiting Edinburgh; nd fusion of the three groups is likely to appeal as a ep towards a society worthy of Edinburgh's ancient undation.

TREATMENT OF OSSEOUS METASTASES WITH TESTOSTERONE

HALF a century ago it was realised that cancer of he breast was associated with activity of the ovaries; nd their removal was suggested as a remedy. Ovarictomy was sometimes followed by improvement but the esults did not seem good enough to establish this as practical method of therapy. Occasionally the growth n the breast itself regressed but metastases appeared o be beyond control. At that time radiography was not ar enough advanced to show accurately the presence or xtent of metastases in bone.

The hormonal treatment of mammary cancer still lemands careful consideration. It has been proved hat the growth of mammary cancers in mice can be revented, or at least delayed, by removing the ovaries n early life; and the disease does not arise in animals ubjected to the continued application of testosterone n sufficient quantity. In both instances the output f œstrogen would be curtailed by the treatment and his probably accounts for the reduced incidence of ancer. However, once a mammary cancer has developed its continued growth is not as a rule inhibited by androgen. Such facts do not prove that androgens are useless remedies for mammary cancer; and Adair[1] contends that testosterone, though not a cure, may sometimes bring considerable relief to women with cancer of the breast when bone metastases are present. Adair records his experience with 200 patients treated in this way. He injects 100 mg. of testosterone propionate three times a week for eight to ten weeks. In most cases of mammary cancer, he says, no benefit is derived from this treatment other than the temporary feeling of well-being which testosterone ordinarily produces. On the other hand, a most striking improvement is obtained if osseous metastases exist, the pain and lack of sleep they cause being quickly relieved, while the rarefied areas seen in the affected bones by radiography become normally dense once more. At the same time the level of calcium in the blood falls and the level of alkaline phosphatase rises.

These results from an authoritative source lead at once to a comparison with the good effects which follow castration or the administration of œstrogen in prostatic cancer with metastases in bone. It is hoped that further reports on this kind of treatment in appropriate cases of mammary cancer will soon be forthcoming.

INHIBITIONS OF THE RUSHCLIFFE COMMITTEE

A LETTER in the *Times* of July 2 drew sharp attention to the discrepancy in the rates offered to trained nurses willing to undertake part-time work and the current rates for a “ char.” For a char the minimum rate asked is 2*s*. 6*d*. an hour, but when a trained State-registered nurse offers her part-time service in a hospital she is offered 2*s*. 3*d*. in accordance with the Rushcliffe scale. It seems obvious that the rate for part-time nurses should be raised to a level appropriate to a woman of professional status who has undergone a long training: and a sessional fee, or something of the kind, should be substituted for a rate per hour.

The payment offered to part-time nurses is not the only bone of contention. Sir Ernest Graham-Little recently suggested in the House of Commons that one of the main causes of the maldistribution of nurses is the flat uniformity imposed on hospitals in regard to rates of pay—a point which has been made in our columns more than once. The great teaching hospitals, which have always had, and still have, waiting-lists for nurses, are now required to offer exactly the same pay as the struggling local-authority unit with half its wards closed for lack of nursing staff. The Rushcliffe policy of uniformity has swept away all the differentiation which formerly helped to secure a better distribution of nurses. The memorandum issued by an authoritative group of doctors in the municipal health services[2] urged that a lifting of this ban, even if only within agreed limits, might go far to improve matters. In the case of student nurses, for example, hospitals suffering from shortage of staff would be at once permitted to increase the allowance from the present £55 for the first year rising in the second and third years, to a flat £100 per annum throughout the three years of training. The scales proposed by the Rushcliffe Committee are not adequately related to the situation we have to meet. What is the trouble? And what is the prospect of some action being taken promptly to remedy it? The trouble seems to be, as far as the outsider can diagnose it, that the industrial representatives on the committee would willingly see nursing recruits paid on a scale comparable with the earnings of girls of the same age in industry; local-authority representatives hesitate to authorise a heavy rise in the expenses of the employing hospitals, even though it be only until the appointed day; while the

nurses' representatives are anxious to maintain the professional standing of nurses and fear that pay at industrial rates would once and for all stamp entrants to nursing as hospital servants rather than professional students. This fear is perhaps less justified than it was twenty years ago, and is likely in the course of a few years to become groundless. In the future most students will probably be subsidised during training at rates appropriate for a modest standard of living, and nurses will take their place beside medical students in this respect. At present the particular difficulty about part-time rates of pay seems to turn on the belief that the interests of the whole-time staff would be prejudiced by an increase in the part-time rates, which are now calculated as a proportion of the pay of the whole-time staff. There might be substance in this objection if upward movement of the rates of the whole-time staff had to be ruled out of account; but when it is patently only a matter of time before all-round increases are granted, objections on this ground lose their force.

Surely the time has come for the Minister to accept outright the financial responsibility which will be his in any event after the appointed day? Let him accept responsibility not merely as now for 50%, but for 100% of the cost of any increases which meet with his approval. This would at any rate eliminate the complicating effects of local-government finance on what is certainly a matter of national urgency.

COMPENSATION FOR THE TUBERCULOUS NURSE

It is possible for a nurse to become infected with tuberculosis from an outside source; but where she develops the disease after being in daily contact with some 20 or 30 cases of open tuberculosis the probability is that her illness is a direct result of her work, and Dr. A. Lisle Punch has cogently urged the need to consider her legal right to compensation.[1] Under the existing law two ways are open to a nurse who seeks compensation. She may claim in negligence (and possibly, we may add, for breach of statutory duty on the part of the hospital authorities who employ her). But a claim in negligence is hard to establish, and Dr. Punch believes that few nurses do in fact develop the disease as a result of negligence. She may also claim under the Workmen's Compensation Acts; but here she must not only prove that her disability is a direct result of her work but also that she met with an accident—i.e., she must establish an occasion, or series of occasions, on which she became infected. To show how uncertain the nurse's rights are at present Dr. Punch cited two cases in which he has given evidence. In both the court accepted the view that the applicant contracted the disease as a result of her occupation. But in the first the judge found himself unable to award her compensation because he held that she had failed to prove an accident. In the second the judge awarded her compensation on the grounds that every time the nurse entered a ward tubercle bacilli assaulted her lungs, and in his view each of these assaults constituted an accident within the meaning of the Act. Dr. Punch, while reluctant to express an opinion as to which of these findings was the sounder law, holds that unless we can reassure nurses as to their right to compensation we shall not persuade them to take up tuberculosis nursing. He admits the possibility of a nurse contracting the disease outside the hospital (a contention which has also been put forward in cases of nurses working in infectious-diseases hospitals); but he argues that the overwhelming probability that she has become infected in the course of her work should be sufficient to ensure her obtaining compensation.

These uncertainties will be removed by the Nati Insurance (Industrial Injuries) Act, 1946, whereof sec 55 provides insurance against certain diseases, to "prescribed" by regulations, being diseases due to nature of the insured person's employment. The is expected to come into operation on some date year, and it will apply only to diseases developed that date. It states that regulations may create legal presumption that a "prescribed disease" is due (unless the contrary be proved) to the nature of the employment where the person has been in a "prescribed" occupation for a "prescribed" length of time before the disease is developed.

A BRITISH CANCER JOURNAL

The first number of the new *British Journal of Cancer*, official organ of the British Empire Cancer Campaign, was published in March. The journal, a quarterly, is the first in this country to be devoted solely to cancer.

The need for a specialised journal, which had been growing for some time, became acute during the war years. The synthesis by Kennaway and Cook of the carcinogenic chemicals some ten years previously stimulated an enormous amount of research here and in other countries. Their discoveries were followed by several in America dealing with pure-line breeding and hybridisation of mice with a high incidence of mammary cancer, and by Bittner's disclosure of the tumour agent in mouse's milk. An outlet for the volume of work had to be found in the two British journals of general pathology and bacteriology, the American journals of cancer research, and a variety of other publications. Thus, for the lack of special journals, the papers were widely scattered; according to Prof. E. L. Kennaway, writing in 1941, contributions to cancer research in the British Empire alone were dispersed in some sixty journals and annual publications.

The new journal may help to concentrate some of this vast literature. With a pleasing pale green cover, it has a similar format to the *Journal of Experimental Pathology and Bacteriology*, and is published by the same firm, Messrs. H. K. Lewis. Microphotographs, in their familiar frames of mourning, are very well reproduced. Rapid publication of new work is aimed at—a gratifying feature in a subject where experiments may take two to three years to complete, all data a long time to collect, and therapeutic trials at least five years to evaluate. Authors represented in the present issue must feel themselves generously treated after the severe war-time restrictions and rationing of space.

STERILISATION OF CONTAINERS

Many substances for injection are supplied in glass ampoules with gummed labels attached, and a correspondent justly complains that such containers are difficult to sterilise since boiling is usually not permissible owing to the nature of the contents. Gummed labels are certainly unsuitable for this purpose, and instructions for use or identifying marks should be etched on the surface, as is the practice of many manufacturers.

The sterilisation of containers presents other difficulties which are not so simply overcome. The ampoule has an easily cleaned surface and its contents are used once only at the time of opening, so it is less subject to criticism than the rubber-capped bottle whose contents are frequently sampled. In less austere days rubber-capped bottles could be supplied with a detachable cap containing an absorbent pad which was kept moist with an antiseptic solution. Today such containers are not often seen and the cap must be cleaned and wiped with an antiseptic before each puncture. Ampoules, on the other hand, can be stored in antiseptic solutions, such as 0·5% formalin or 1 : 1000 biniodide of mercury. But

Authors represented in the present issue must feel themselves generously treated after the severe war time restrictions and rationing of space.

STERILISATION OF CONTAINERS

Many substances for injection are supplied in glass ampoules with gummed labels attached, and a correspondent justly complains that such containers are difficult to sterilise since boiling is usually not permissible owing to the nature of the contents. Gummed labels are certainly unsuitable for this purpose, and instructions for use or identifying marks should be etched on the surface, as is the practice of many manufacturers.

The sterilisation of containers presents other difficulties which are not so simply overcome. The ampoule has an easily cleaned surface and its contents are used once only at the time of opening, so it is less subject to criticism than the rubber-capped bottle whose contents are frequently sampled. In less austere days rubber-capped bottles could be supplied with a detachable cap containing an absorbent pad which was kept moist with an antiseptic solution. Today such containers are not often seen and the cap must be cleaned and wiped with an antiseptic before each puncture. Ampoules, on the other hand, can be stored in antiseptic solutions, such as 0·5% formalin or 1 : 1000 biniodide of mercury. But

THE OPERATION FOR CONGENITAL COARCTATION OF THE AORTA

A PATIENT'S EXPERIENCE

H. T. VAN DIGGELEN
M.B. Cape Town

No description of the symptoms of congenital coarctation of the aorta is necessary. Mine was a classical case, complete with well-developed collateral arteries over the back and abdomen, chronic headaches, large pulsations in the neck, and no pulsations in the legs except a very weak femoral pulse. At 30 years of age my blood-pressure was 200/120 mm. Hg.

Treatment being imperative, it was decided to consult Dr. C. Crafoord, the Swedish thoracic surgeon in Stockholm. I had heard that he had operated successfully on 12 cases out of 13; so I travelled to Sweden, and Dr. Crafoord first saw me on Oct. 2, 1946, and arranged for my immediate admission to the Sabbatsbergs Hospital for a general investigation. This began on Oct. 4 and included:

(1) *General Physical Examination.*

(2) *Electrocardiography* at rest, after severe exercise, and after breathing a mixture of carbon dioxide and oxygen for 10 min. (I was almost in extremis after 7 min.).

(3) *Phonocardiography.*

(4) *Oscillography.*—For this an ingenious machine, perfected by Dr. B. Ejrup, of the Södersjukhus, was used. It is worked with compressed air and electricity and, using two Baumanometer cuffs on each limb, draws a continuous graph of the arterial pulsations and measures their amplitude and the blood-pressure before and after exercise. The exercise consisted of running up and down four flights of stairs eight times for each of the four limbs. I had visions of a burst aorta, but this was unfounded. The response to exercise showed enormous amplitude of the pulse and high blood-pressure in the arms; but in the legs hardly any pulse or blood-pressure could be measured.

(5) *Cardio-angiography.*—This is the most severe of all the examinations, but also the most interesting. The patient is placed in the X-ray apparatus in a sitting position, with a box in front of the præcordium which enables rapid changing of the X-ray plates. The cubital vein in the right arm is then dissected out under local anæsthesia, and a large metal cannula is inserted. By this means 50 c.cm. of an iodine preparation is injected as rapidly as possible, during which time about five X-ray plates are exposed while the patient tries to hold his breath. The sensation due to the iodine preparation is really terrible. One feels as though one is choking to death. The head feels like a balloon, and the entire body seems to be on fire. Luckily the effect passes very rapidly, and the experience was worth it, as I was able to see beautiful radiograms of the aorta showing the coarctation.

(6) *General X-ray examination,* including barium swallows.

(7) *Kymography.*

(8) *Miscellaneous*—dental, ears, nose, and throat, basal metabolic rate, rate of blood-flow, kidney-function test, urine, stools, and detailed blood examinations.

I was much impressed by the precision and efficiency of the Swedish doctors and nurses, who carried out each test with the greatest care.

Much of the preliminary investigation was extremely exhausting; the reason for it all was to find out exactly how much cardiac and respiratory reserve the surgeon could depend on during the operation, and so far as possible to determine the condition of the arterial walls; but it made me realise a little what patients have to suffer at times.

PREPARATION FOR OPERATION

On completion of the investigations on Oct. 8 Dr. Crafoord decided to operate at once. I had great confidence in him and the people about me, so I slept peacefully that night. On the morning of the 9th I was awakened with an injection of 'Omnopon' and scopolamine, and was still awake when wheeled into the theatre at 8.30 A.M. The injection must have had a good effect, as there was a complete absence of fear. Expecting an injection of 'Pentothal,' I received a rude shock when the anæsthetist began to anæsthetise my throat instead, and passed a closed-circuit intratracheal tube without the aid of any further anæsthetic. Luckily he had no difficulty in passing the tube, but the sensation was nevertheless ghastly, as suffocation appeared to be imminent, until I remembered that the tube was hollow. Thus reassured, breathing presented no further problem.

The sensation when the cyclopropane was turned on was quite pleasant, and very welcome unconsciousness ensued in a few seconds. The administration of the anæsthetic in this manner was an extra precaution to make certain that there would be no respiratory spasm. The only other anæsthetic used was curare. Afterwards there were none of the ill effects, such as vomiting, usually associated with long anæsthesia. The anæsthetic lasted for about seven hours, and the operation six hours, extra long anæsthesia being required for postoperative radiography.

POSTOPERATIVE COURSE

When "coming round" that evening I noted my rather shocked condition, but I was too weak and exhausted to care. The pain in the wound was intense. The incision followed, in an S-shaped curve, the course of the left fifth rib from its junction with the spine to the costochondral junction, and the rib had been removed. I had to lie with my weight on the wound, and no amount of soft pillows and rubber mattresses seemed to help.

Knowing a good deal about the subject I was at first terrified that the sutures in the aorta would pull loose, but one must experience this to realise what it means. To make matters worse I was told to force myself to cough every hour or two to clear the respiratory passages, as the left lung had been collapsed during the operation. As can be imagined, this intensified not only the pain but also the fear. The fear soon passed, however, when I was assured that the sutures would "hold until doomsday."

It was a great satisfaction to be shown the piece of aorta that had been excised. The specimen was about 1 in. long, and the stricture, which could plainly be seen, admitted a match-stick with difficulty.

Though there was no infection or any other complication, a full course of penicillin lasting sixteen days was administered to prevent the possible onset of pneumonia. Altogether I had 158 injections, including the morphine given during the first five days. These injections did not worry me particularly; they burned somewhat, but there is certainly no reason to become neurotic about them as some patients do.

The postoperative period was uneventful, but one or two nursing points may be of interest. For the first seven days I refused all food except frequent sips of milk and thus lost many pounds in weight.

With regard to bed-pans, knowing how abominable they are I refused to have a bowel action for the first six days. The result on the seventh day was disastrous, and I vowed never to use a pan again. On the tenth day I was allowed to get out of bed with the help of a nurse and sit on a portable bucket affair with a comfortable wooden seat. It had a lid which fitted over the seat after use and an ordinary bucket handle for carrying it. The seat was detachable.

The nurses earned my deepest gratitude by not forcing me to eat when I did not want to, and equally by not making me have an unnecessary bowel action, when to have had one would have caused me great discomfort.

Sitting up in bed as far as possible seemed to be the position of most comfort, as in this way much of the weight was taken off the wound. One cannot lie on either side, as this seems to cause undue strain on the place where the fifth rib should be, and thus much discomfort.

After three weeks I was able to get out of bed and walk about, and I left hospital at the end of four and a half weeks. Five days later I could walk three miles without any ill effects.

The blood-pressure dropped immediately after the operation to 155/95 mm. Hg in the arms, and rose to 120/80 mm. Hg in the legs. By Nov. 27 the pressure was 125/80 mm. Hg in the arms and 130/85 mm. Hg in the legs. I have been back at work now for five months and have none of the previous distressing symptoms. My blood-pressure is 150/80 mm. Hg, and there are good pulsations in the dorsalis pedis arteries. All the enlarged collateral arteries collapsed immediately after the operation. Dr. Crafoord has recently assured me that, after observing his other cases for the past two years, he feels sure that at the end of a year the pressure should become normal and remain so. There is no reason why this should not be so, but it takes time for the previously poorly used and underdeveloped arteries to adjust themselves to a full flow of blood.

TECHNIQUE OF OPERATION

Before I left hospital I was fortunate enough to witness one of these resections of the aorta, and it may be of interest if I mention a few of the main points.

The surgeon works with a highly trained team of three assistants besides an expert theatre staff. The muscles are cut between clamps with a diathermy knife. Any large arteries that remain uncoagulated are then tied off before the clamps are removed. This prevents a great loss of blood from the cutting of the many enlarged collateral arteries. By removing the fifth rib a perfect exposure is obtained.

The most difficult procedure is to dissect out the aorta and the right and left intercostal arteries, especially those on the right. This must be done thoroughly, as the aorta must be well mobilised so that the cut ends can be sutured together without tension after a good inch has been cut out. The intercostal arteries are not tied off, but are preserved, which makes the task twice as difficult.

The remains of the ductus arteriosus must also be divided. The aorta, which takes an S-shaped bend below the subclavian artery in these cases, then springs back into its normal position. Before being cut the aorta is manually compressed for 5 min. while the patient's reactions are carefully noted.

In most cases the left subclavian artery is greatly enlarged, and its junction with the aorta comes very close to the stricture. When the aorta is clamped, the upper clamp includes the base of the subclavian artery, and still there is very little space left for suturing between the clamps.

In suturing the cut ends of the aorta the histological structure is preserved as much as possible by opposing intima to intima, media to media, &c. The sutures should pass between intima and media if possible and not enter the lumen.

The clamps can be left on for a good hour if necessary, as the collateral arteries take care of the circulation.

It is most difficult to effect a watertight joint, and it was emphasised during the operation that one should practise on many dogs before attempting the procedure on a human being. It may even be found that at first some of the dogs will die, because of a leaking suture line.

I wish to express my gratitude to all the doctors and nurses in Stockholm who so ably saw me through the operation and convalescence, and by their kindness, consideration, and knowledge of English made my stay there such a happy one.

ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND

THIS association met in Oxford last week under the presidency of Sir Hugh Cairns.

Speaking before several hundred members at the annual dinner, held in the hall of Christ Church, Prof. GEOFFREY JEFFERSON, F.R.S., said that the meeting had done a great deal to revivify the association and "make us feel that it really does matter." Moynihan's wish had been that British surgery should never be defaced by the jealousies too often seen in Europe, and through his dining club and the association he had done much to prevent that happening. With growth in size the association had lost something of its original sociable intention, but it had gained by the opportunity for larger numbers to meet and hear what is going on. It was rather fun, he felt, that two specialists such as himself and the president should be proposing and responding to the toast of The Association: it was a sign that medicine, surgery, and neurology are really all one subject; and he believed that recruits to the specialties should be drawn in the proper way—from general surgery. The President—product of a marriage between Australian vitamins and Oxford culture—was a strong man both physically and mentally, with a relative contempt for financial ends. "And we shan't do far wrong when we praise men for that."

Sir HUGH CAIRNS agreed that the association should be grateful to its founders for their effort to promote friendship and interchange ideas among surgeons. At Oxford, he said, the clinical departments had emerged only nine years ago, at the bidding of the "Cowley father of modern medicine." "In this university institutions and departments don't mature quickly," but he hoped that the right conditions would develop within the next ten years. Some teaching schools put their emphasis on the needs of the patient, and some on the needs of the undergraduate student; but universities as a whole put it on research. At Oxford it was felt that the primary duty of a teacher is to create new knowledge, and the university atmosphere was one of criticism. The teacher must have his records, his table, his desk, his leisure. The day had not yet arrived when a surgeon could excel in the ward and the laboratory at the same time, but any attempt at standardisation should be resisted. After all, Lister's inaugural lecture had been on fermentation. Science had since become far more complex, but important advances could still be made by any surgeon prepared to be a perpetual student. "Let us mix our surgical types," said the president; "it is our English way."

Sir ALFRED WEBB-JOHNSON, P.R.C.S., proposed the health of The Guests, who included Dr. L. Bazy, Prof. René Leriche, and Prof. W. Noordenbos (newly elected honorary fellows), and Lord Nuffield. Sir RICHARD LIVINGSTONE, vice-chancellor of the university, replied to the toast. The surgeons from France and Belgium attending the dinner included Prof. H. E. F. Albert, Prof. R. Danis, Prof. J. de Formestraux, Dr. Lortat-Jacob, Prof. L. Mayer, and Prof. J. Morelle.

Prof. J. R. Learmonth, of Edinburgh, will be president next year.

NATIONAL (WAR) FORMULARY REVISED

A LARGE number of additions, alterations, and deletions will be made in the forthcoming third edition of the *National (War) Formulary*. The additions include, besides the newer drugs listed below, some that were in short supply during the war; it has been possible to replace the liquid extracts of colchicum, hyoscyamus, ipecacuanha, opium, quillaia, and stramonium by the corresponding tinctures.

ADDITIONS

Penicillin preparations.—Auristillæ, cremor, guttæ, injectio (aqueous), injectio oleosa, naristillæ, nebula, oculentum, *pulvis penicillini* et sulphathiazoli, solvella, trochiscus, and unguentum. The oily injection may be made with a basis containing beeswax and either arachis oil or ethyl oleate. When made with the latter solvent it is less viscous and easier to inject.

Vitamin preparations.—Capsula pluravit (containing vitamins A, B_1, B_2, C, and D), tabella nicotinamidi, tabella acidi ascorbici (now contains 25 mg., but the former 5 mg. tablet remains in the *Infants' Section*).

Hormones.—Tabella dienœstrolis, tabella hexœstrolis, tabella stilbœstrolis.

Sulphonamides.—Guttæ sulphacetamidi fortes et mites, pulvis penicillini et sulphathiazolis, tabella succinylsulphathiazoli, tabella sulphadiazinæ, tabella sulphadimethylpyrimidinæ, tabella sulphaguanidinæ.

Barbiturates.—Tabella butobarbitoni.

Among well-known formulæ now included are: cremor zinci and cremor zinci et ichthammolis; elixir cascaræ; suppositorium bismuthi subgallatis; tabellæ ferri phosphatis cum quinina et strychnina; tabella ferri phosphatis composita (sugar-coated); cremor zinci et olei ricini (*Infants' Section*); pulvis aluminis et zinci (sterilised and packed for each application).

There is a new tabella paludrinæ and an applicatio D.D.T., which is a solution of the chemical in solvent naphtha, emulsified as a water-miscible emulsion with emulsifying wax—one of the new emulgents.

ALTERATIONS

Most of the alterations represent improvements in the presentation and preservation of the preparations, as experience has shown to be necessary. In some cases names have been made more precise. Liquid extract of liquorice has been added to the haustus paraldehydi, which will prevent confusion with the pure drug. In lotio calaminæ it is not clear why the altered formula should contain the cumbersome quantities of calamine 1 oz. 90 gr. and zinc oxide 175 gr. in 8 fl. oz., nor why the imperial ounce should be thus used, when in other preparations, such as cremor zinci, the quantities are made up to the apothecaries' ounce, 480 grains.

In the *Infants' Section* the doses of several powders and tablets have been reduced.

DELETIONS

The preparations omitted include the following misturæ: arsenicalis, calcii lactatis, ergotæ, ferri arsenicalis, ferri perchloridi, ferri salicylatis, hydrargyri perchloridi, and quassiæ cum rheo.

EX-SERVICE NURSES

FURTHER opportunity for ex-Service men and women with qualifications as first-class nursing orderlies to become State-registered nurses after an intensive course of one year, instead of the usual three years' training, is announced by the Ministry of Health. Twenty-six shortened courses have been in operation throughout the country since last autumn; they are being taken by 738 candidates—511 men and 227 women. Of 164 who sat the preliminary examination last February, only 2 failed completely. When the present students take their final examination next October there will be vacancies for other ex-Service men and women to take this shortened course.

Men are paid at the rate of 92*s.* a week, with a deduction of 30*s.* a week to cover board and lodging, or 20*s.* in the case of a married man with home responsibilities. Women students get £90 a year, with free board and lodging or a living-out allowance of £80 a year if they are living at home. Examination fees for students are paid, and there is provision for free medical treatment and fares. Men and women may be given accommodation at the training centre or they may live in their own homes or quarters near the course. Only those with the rank of a nursing-orderly or nursing-member class I, leading sick-berth attendant, or leading aircraftwoman or leading aircraftman in the trade of nursing orderly who have had at least two years' ward experience under trained nurses are eligible. Men and women with these qualifications who are still in the Forces should apply through Service channels. Others should write to the secretary of the Ministry of Health, Whitehall, S.W.1.

Modern Care of Old People

VII

RESEARCH AT ST. JOHN'S HOSPITAL, BATTERSEA

THE process of ageing is being studied in various centres nowadays, notably by Prof. F. C. Bartlett at Cambridge and Dr. J. H. Sheldon at Wolverhampton. It is astonishing how little is known even about the common illnesses of the old—" the forgotten diseases," as they have been justly called. At St. John's Hospital, Battersea, Dr. Trevor H. Howell is making studies of such common conditions as chronic bronchitis and rheumatism.

BRONCHITIS

The old people admitted to the chronic bronchitis wards of this hospital answer a full questionary about the development of their illness; their sputum is measured daily, and examined bacteriologically every week, and their response to all the usual expectorants is studied systematically. The blood-count, hæmoglobin, blood-sedimentation rate, alkali reserve, blood-urea, and circulation rate are studied in every case, not because they are likely to be abnormal but because regular studies of them in old age have never been made. Similar investigations are made in a control series of old people who are not bronchitic; and the chests of both groups are examined radiographically, so that it will be possible to assess the pathological against the normal findings in old age. In the post-mortem room the morbid anatomical changes in the old, and especially in their lungs, are being examined; and an outpatient clinic for chronic bronchitics has just been opened which should bring a much wider range of patients under review. This long-term piece of research may be expected to fill many gaps in our knowledge.

STUDIES OF INCONTINENCE

Another investigation being made at this hospital has yielded unexpected results. Using the cystometer, Dr. T. S. Wilson began a study of the incontinent bladder. With this method the bladder is infused and the pressure in it measured by a water manometer. The original aim was to discover at what stage of distension the bladder was liable to contract. The first case, an old man, had frequent contractions of considerable amplitude—pressures up to 120 cm. of water registering on the manometer—with no apparent control or previous desire to micturate. After the infusion the patient announced that he thought he had better control of his water; and a subsequent infusion showed that the contractions were now occurring at a later stage of distension than they had done the first time. Again the patient noted improvement after the infusion; and study of a group of patients has shown that such slow distension of the bladder can be a very successful form of treatment for incontinence, especially in old men. The bladder becomes capable of holding more urine, and the nerve-endings seem to become less irritable. Desire to micturate, often lost in these cases until the bladder contraction has already begun, returns and precedes the contraction by several minutes, thus giving the patient time to get to the closet. The result has been that several old men who had been incontinent, and therefore miserable, now have good control of micturition, and the ward atmosphere has become much more cheerful in consequence.

RECOVERING MOVEMENT

At this hospital there is, in any case, no sign of institutional apathy. The patients are alert and interested, as always happens where treatment is active and the nursing staff keen. Hemiplegics are got on to their feet early—in one case within a week of the stroke—and so never develop contractures. The physiotherapist demonstrated a slightly different type of walking machine from that seen at the West Middlesex—a type in which the patient s steadied and supported by crutch bars under the armpits, and is obliged to walk upright instead of leaning forwards.

Arthritics, even those who have been in bed for many years, after being admitted to this hospital as hopeless cases, are responding to active treatment—to injection of fixed joints with procaine and lactic acid, to regular physiotherapy, and to occupational problems which can only be solved by making use of the stiff joints. They are getting up, walking, making pleasant and useful things with hands that had seemed beyond all use, and recovering their spirit as their physical powers recover.

Occupational therapy is well developed, and even old contracted limbs can often be brought back into limited use when set to the appropriate task. The nursing staff have responded, as usual, to a keen medical staff, and take the same pride in the progress of the patients, and have the same stern professional standards about the revention of bedsores, as nurses at the West Middlesex.

Reconstruction

THE NATIONAL SITUATION

A Positive Policy for Food[*]

FROM A CORRESPONDENT

THE Government have given no hint that they ppreciate the urgency of a drive to increase production of food at home to the level required to reduce materially ood imports from abroad. With their eye on the law of diminishing returns they still seem to believe in the danger of pushing food-production to the point where we should be paying too heavy a price. While giving moderate encouragement to the farmer by the Agriculture Bill, they pin their faith to an export policy which is to give us the wherewithal to buy food abroad as of old, and to the hope of a world food surplus. In other words, they seem to be banking on unlikely success with exports, or on a fall in world prices for food. Such a fall may occur; but to bank on it exposes our whole economy to the hazards of a world market in food which shows little sign of reverting to its old pattern, and involves us in a one-sided bargain in which the food-exporting countries have the upper hand. With every other nation determined to regulate its economy in its own interests, the hope of abundant cheap imported food grows fainter every day, and common sense demands that we adjust to the changed conditions before it is too late.

Before the war we produced about 40% of our own food; and if we are to increase this 40% to about 80% a far greater effort is needed. It means something like a doubling of the productive resources devoted to agriculture. The incentives must be stepped up, and priorities at present afforded to the export industries modified accordingly.

INCENTIVES TO FOOD-PRODUCTION

Knowledgeable people agree that we could achieve a great increase of food-production at home; but they differ as to the relative urgency of the measures needed to bring it about. By some first place is given to the need for more man-power on the land, by others to the need for capital and mechanisation, and by others to the failure to provide houses for farm workers. The differences as to means must not obscure the overriding need for greater monetary incentives than we are at present giving.

Take the problem of man-power. One-eighteenth of our man-power is at present engaged in agriculture and allied pursuits. Despite accessions there is still a steady leakage to the towns. The anxiety as to what is going to happen when the German prisoners go is a striking commentary on the wage level. It is true that the minimum wage of the farm worker has been raised from 35s. a week in 1939 to £4 10s. a week today, and that many farm workers get, with their cottages and other perquisites, more than this. But the wage structure of agriculture is still such that it cannot compete with the towns. Our young men, mixing with their urban fellows in the Forces, discover that in the towns they can find work at rates that make the farm worker look foolish: £5 a week minimum for the raw hospital porter, £6 or £7 for a capable man in a multitude of commercial and industrial undertakings. Is it surprising that we are short of labour on the land?

Or take capital for mechanisation and for the many other items that make for efficiency. A great change is in full swing, and everywhere the tractor is replacing the age-old methods of cultivation. But whereas in most industries the age of mechanisation occurred when profits were available for the purchase of machinery, in agriculture the climax of the change has coincided with an era of unprecedented taxation. The farmer is not exempt from income-tax, or from the incidence of purchase-tax on much that he has to buy from the towns. A great brake is thereby applied to the process in this country—far greater than elsewhere—just at the time when it is most desirable for us to speed up the transition. The physical shortage of equipment for mechanisation is bad enough, but when on top of it there is the pressure of taxation at present levels the farmer is doubly handicapped.

Or take housing. Is not the difficulty here quite as much a matter of money and of the traditional wage and status of the farm worker as of physical shortage? We hear a great deal of the need for houses for farm workers: and often of course it is true that the houses simply do not exist where they are required. But as often as not the trouble is seated deeper than this. No-one can travel about the countryside without realising that comfortable little houses exist almost everywhere—at any rate in Southern England—which are eminently suitable for the farm worker but which are otherwise occupied. The simple fact is that other members of the community, even week-enders, have slipped into the houses with which the countryside is dotted. The tradition of the labourer's cottage is strong in agriculture, and is a reflex of his traditional wage. If we increase his wage to a figure comparable to that of the small shopkeeper or municipal employee, he will be able to compete with others. More, he will be given the strongest of all incentives, the hope of possessing a home and a garden of his own of which he may be proud.

It is mainly a matter of money. For over a century our agriculture has been the victim of the industrialisation of England and of the cheap food from abroad, which is now at an end unless the export drive suddenly achieves a measure of success quite beyond the bounds of practical probabilities. The remedy is clear and straightforward. The proportion of our resources devoted to agriculture must be increased, and the reward to the farmer for his produce must be stepped up until a new equilibrium is attained which enables him to pay wages fully equal to those of other occupations (and a little higher, until that equilibrium is attained); which provides a margin permitting of mechanisation, and experimental mechanisation at that; and which, besides this, offers an incentive to able men to go into farming and make a success of it. In other words the cost of food to the community will have to go up.

FOOD PRICES AND THE SUBSIDIES

If food producers are to have more money, we must either have higher prices to the consumer or we must contribute heavily through subsidies. A rise in the cost of food to the consumer does not square with our present policy of redistributing the national income, and we shall therefore have to face a continuance of, and perhaps even a temporary increase in, food subsidies, which at present amount to nearly £400 million, a sum equivalent to 3*s.* in the £ income-tax.

---

[*] Two previous articles appeared on March 15, p. 340, and May 17, p. 686.

The nature and effect of the existing subsidies is as yet little understood. The popular view is that they represent a helping hand extended by the community to the farmer, for which he ought to be grateful. Nothing could be more mistaken: no view of the subsidies which fails to couple them with the control of prices can begin to approximate to the truth. The fact is that, whereas the old laws of supply and demand still operate over the greater part of our economy, we have imposed a system of price control on both imported and home-grown food. So far as the farmer is concerned, the principal effect—far transcending the subsidies—has been the elimination of his right to sell to the public at prices dictated by the relative scarcity of his produce to other goods. Having deprived the farmer of this right, the State has had to rectify the situation by giving the farmer subsidies which to some extent compensate him for the loss of profit. The subsidies are therefore properly seen as but the reflex of the control of prices. The farmer would certainly be better off with a free market and no subsidies—at any rate in conditions such as those which now prevail when there would be no danger of the market being flooded with cheap food imported from abroad.

But this is not the whole story. The price-control-cum-subsidy structure is essentially an emergency measure, and the level of prices to the consumer which it is designed to secure presupposes a return to the conditions of 1939—i.e., the resumption of imports of food from abroad on something like the old scale and at something like the old prices. Only in such circumstances can it be ended, unless some other radical change comes to the rescue. If the loss of our foreign assets and the fading prospects of the export drive preclude such possibilities, we are thrown back on our own resources. What hope is there then of dispensing with the subsidies, and so freeing the Exchequer of a burden which is throttling incentive all along the line?

Fortunately there is in progress another radical change which holds out hope and which might offer the basis for a rational policy—which may, indeed, over a decade or so, bring the cost of food-production at home into line with the level of prices that the consumer can be asked to pay. Great technical advances are being made in agriculture. One has only to list the implications of the biological and biochemical sciences to realise their immense potentialities. The still new science of genetics as applied to plant life and seed-production is in its infancy. The work of Sir George Stapledon and others in the improvement of grass has yet to revolutionise the produce of our marginal land. Artificial insemination of livestock is being developed with great rapidity. The work on the control of virus diseases and insect pests being done at Rothamsted and elsewhere is likely to result in a dramatic increase in the yield of our fields. These possibilities are not far-fetched and idle dreams.

How then does this prospect affect the food subsidies? Surely, within a fairly long period, say ten years, we may reasonably expect the cost of food-production to have been markedly reduced—perhaps sufficiently to offset the increases in the reward to the farmer now needed to step up our agriculture.

A DOUBLE POLICY

Some attempt, however tentative, to suggest the shape of a positive programme seems to be called for. A double policy seems to be indicated. First, an immediate and substantial increase in the subsidies for home-produced food for the next two or three years, to carry us over the immediate period of transition—designed to bring the maximum effect in increased production. They should not, for instance, be frittered away in petty reliefs to the consumer such as the recent reduction in the cost of the weekly ration of cheese from 1½*d.* to 1¼*d.*). Secondly, a progressive scaling-down of the subsidies by something like 10–15% per annum over the next eight or ten years, designed to give the community the advantage of the technical progress in agricultural methods. Let the subsidies rise to a total of some £500 million for say the next two years, and thereafter decline over the following decade by some £50 million per annum. It is a heavy burden on the Exchequer, and some saving may be possible on the side of the bill which relates to imported food. But at least such a programme offers the prospect of a steady lightening of the burden.

For the policy to be successful a closer integration between the Ministries of Food and Agriculture seems to be essential. In our present circumstances it may be necessary that the Minister of Food should tour America buying up what he can; but in the longer run it will be necessary to see that control of imports is vested in the Ministry responsible for the control of prices of home-grown food. Internally, too, there is room for study of the effects of subsidies upon production, since much of the subsidy money is now poured away irrespective of its uneconomic effects in encouraging production unsuited to the locality. The system is too simple; the pattern of food-production, on the other hand, is complicated, and there are subtle inter-regional relationships which a simple flat-rate system brushes aside. If the subsidies have come to stay with us yet awhile, the improvised war-time methods must be overhauled, and the whole scheme subjected to a detailed review in which the views of the agricultural experts must prevail over the political anxieties of the Ministry of Food.

The prospect as a whole contains much that is grim. A long period must elapse before a new balance is attained, and our much-vaunted industrial expansion may meanwhile suffer some check. But it is a big canvas, and there is much in the picture besides occasion for gloom. There is a story told of Mr. Churchill in the dark days when France was crumbling in 1940. Colleagues round the Cabinet table drew long faces, and a gloomy silence settled upon the meeting as the prospect of battling on alone was examined from one angle and another. "For myself," said Mr. Churchill rising from the table, "I find it rather stimulating." This surely is the attitude we need to face a future which holds out no prospects of the continuance of imported foods purchased with the interest on our foreign investments, and which certainly involves an upheaval of many of our accepted ideas.

The end of England as a great industrial exporting country? No; for if we continue to equate our exports with our imports of raw materials, as we did before the war, we shall still be carrying far more than our proportion of international trade.

There is in sight a better balanced community, and an end to the drift to the towns with all its dubious social consequences. For 150 years past voices have been raised to protest against the spoliation of England, and the desolation and poverty of our rural community. Is it now at long last true that we have topped the curve of the graph? Will not the change bring with it a healthier, happier, and more independent Britain, fitted to show the world how to enjoy the benefits and at the same time to curb the consequences of the industrial revolution?

In England Now

A Running Commentary by Peripatetic Correspondents

I HAVE just finished reading the fiftieth biography since I started taking notes on them two years ago; they include biographical records like Agate's *Ego* and Arnold Bennett's *Journals*, both of which show a self-satisfied sun moving serenely in an extremely small orbit. Quite a lot of my time has been spent on the "bought biography," commissioned by the family or by the subject himself, and little more than an expanded synopsis from *Who's Who*. The same may be said of the "Life" by wife, son, or sib; these should be treated as detective novels, the reader making deductions from what the too diabetic pen left out. Even from these one can get clues that lead to the soul—e.g., A. J. Balfour's father died (from tuberculosis) when he was seven, but he couldn't remember him; Lord Melchett took a first in poker at Cambridge; Parnell was much puzzled over *Alice in Wonderland*; "A curious book," he said after a long and serious study. The short scholarly biographies like Lee's Shakespeare or Colvin's Keats have been the most satisfying; when I sat down with Morley, Rosebery, Carlyle, or Garvin my bowels could move neither with hatred nor compassion, there was too much flatus. The hostile mocking biography is usually by a detached alien—Macaulay, Ludwig, Maurois. Sometimes, however, the alien is hypnotised by his subject: Boswell by Johnson, Sorley Brown by T. W. Crosland.

I liked noting physical characteristics: Thomas Hardy couldn't bear to be touched; Wallenstein had a hypersensitive ear; Clifford Allbutt was a visual thinker; Donald Macalister, a senior wrangler, was almost certainly a word and figure thinker; Gordon had no ear for music, but how I sympathise with "A social engagement hung over him like the sword of Damocles"; Havelock Ellis in his *Life* shows himself blind to his own mainspring—the rigid curtailment of his own sex life producing a team of books on sex; Captain O'Shea got "measles" every time he was in financial trouble. I must say I do like to know what my man dies of: Henry Kingsley's cancer of tongue, Flecker's tubercle, Wells's healed tubercle and diabetes explain much. Sometimes one can watch one's subject helping to kill himself—Parson Woodforde by over-eating, Bonar Law by over-smoking, Inchcape by over-bossing. The ideal biography would start with a chromosomatic map and end with necropsy reports and slides, at least half the book being devoted to the first three years, from which the rest must logically follow.

Although our conscious minds do not recognise that great qualities and vices must spring from their opposites—courage from cowardice, sociability from loneliness—yet the subconscious has known this for some million years and refuses to let a too sickly or too bitter mess go to the stomach of memory, tossing it back to the word-strutting consciousness. The only thing I can remember about Northcliffe's life is that he could not bear to get sand between his toes, which makes him laughable but human. That is where most of the clerical biographies fail—Randall Davidson, Lionel Ford, Percy Dearmer, but not so much Dick Sheppard who is more spotty—they lack blacking and lovableness.

* * *

I can remember the late Mr. Griffiths at Addenbrooke's saying "Give her air! Any fool can give chloroform: it takes an anæsthetist to give air." Sitting over a mask giving chloroform or ether in the old days was a very different business from the modern methods. At one time the surgeon could tell the days of the week by the effect the different anæsthetists had on the colour of the patients: Pink Monday was quite different from Black Friday. In those days the surgeon watched the anæsthetist anxiously, and the anæsthetist watched the surgeon intently because he hoped one day to become a surgeon himself. Later, with the extended use of machines which delivered a regular supply of anæsthetic, the anæsthetist became chronically bored. You still see some of these anæsthetists reading their journals during operations; I have heard of one who even wrote a book while supervising a machine-given anæsthetic. Still later a generation of anæsthetists arose who were really interested in their job. The first crop were fascinated with their new machines and were not satisfied until they had invented some gadget and got their names attached to it. But after a time they really got to know why and how the things worked. And now the surgeon can concentrate on the operation without having to keep an eye on the colour of the patient and be prepared to leap on his chest directly his guts stop moving up and down.

* * *

Lucy was a private, A.T.S. She had been in for 16 months. Her actual service, if you added together the intervals when she condescended to return from her frequent A.W.O.L.'s, was about 8 months. Lucy's junior commander thought her "personal habits dirty." This, for a start, was intriguing. I speculated idly on whether Lucy picked her nose or went in for more spectacular vicissitudes. Then I came, lower down in the report, to the words "loose morals." Big stuff, eh? And the M.O. thought she was "a thoroughly bad lot." Hard words, partner.

And what had Lucy to say for herself? We gathered Lucy's dad had been a nasty old man "who must have had a guilty conscience, for he always seemed to think I was up to no good." Lucy was an independent girl and joined the A.T.S. "not because she liked the King but to see Life." Now we were getting warm. Forgiving Lucy's sad deficiency in patriotism, we asked for details. Lucy looked as coy as her layers of rouge and lipstick would allow. "Of course, I'm a married woman now," she sighed. "And a thoroughly respectable one too." we ventured. She rose to the bait neatly. "Well, I know they say I'm a prostitute but it's all due to a misunderstanding, you know." "Oh yes?" we said, mustering all our sympathy. "You see," she went on, "one day I was walking down a street at home—it did have rather a bad name. And suddenly a man, a detective I suppose, came up to me and gave me a bit of paper and said I had to call at the police-court on Saturday. You can imagine how surprised I was!" We nodded our head vigorously. "Well, when I got to the court the old man—I suppose he would be the judge—looked me up and down and said, 'Do you plead guilty to street-walking?' So I says to myself 'Well, I wasn't exactly running,' and like a twerp I says to him, 'Yes your lord.' Then he says, 'I fine you £5 for being a common prostitute.' Me! Common!" We shook our head deprecatingly. "I didn't see much use arguing when he had the police on his side, so I let it go at that. But when I got back to camp there was the whole story up in Part II Orders just like in the *News of the World*, with my name and all. Just imagine! And ever since then none of the girls in the camp would speak to me and all the men kept coming up to me on the quiet and saying, 'What about it?' And so I thought if they were going to give me a bad name I might as well live up to it. I couldn't help it, could I?"

When Lucy had gone I pondered over her story and tried to find a moral. I can only think I must warn my wife that if a strange man tries to give her a piece of paper on the street she should curtsy and say, "Thank you, but I have a piece of paper, and I've got a previous engagement for Saturday anyway."

* * *

I phoned the hospital (and not a little one either) on a Sunday at about 7 P.M. to arrange for the transfer of a case. After a while an educated voice answered. I asked if I could speak to the porter-telephonist; he was afraid not. Then to one of the sisters, or to Dr. S, the resident? Embarrassedly, the voice told me that at this time of a Sunday evening *all* the staff went off to their meal, the phone was switched to one of the floors, and a patient had to answer it. Well, well, in that case could he possibly summon someone responsible, as the transfer was urgent? The patient was charming. "If you wait while I get my other crutch," he said, "I will go and fetch Dr. S." And in a quarter of an hour the doctor arrived.

contribute heavily through subsidies. A rise in the cost of food to the consumer does not square with our present policy of redistributing the national income, and we shall therefore have to face a continuance of, and perhaps even a temporary increase in, food subsidies, which at present amount to nearly £400 million, a sum equivalent to 3*s.* in the £ income-tax.

The nature and effect of the existing subsidies is as yet little understood. The popular view is that they represent a helping hand extended by the community to the farmer, for which he ought to be grateful. Nothing could be more mistaken: no view of the subsidies which fails to couple them with the control of prices can begin to approximate to the truth. The fact is that, whereas the old laws of supply and demand still operate over the greater part of our economy, we have imposed a system of price control on both imported and home-grown food. So far as the farmer is concerned, the principal effect—far transcending the subsidies—has been the elimination of his right to sell to the public at prices dictated by the relative scarcity of his produce to other goods. Having deprived the farmer of this right, the State has had to rectify the situation by giving the farmer subsidies which to some extent compensate him for the loss of profit. The subsidies are therefore properly seen as but the reflex of the control of prices. The farmer would certainly be better off with a free market and no subsidies—at any rate in conditions such as those which now prevail when there would be no danger of the market being flooded with cheap food imported from abroad.

But this is not the whole story. The price-control-cum-subsidy structure is essentially an emergency measure, and the level of prices to the consumer which it is designed to secure presupposes a return to the conditions of 1939—i.e., the resumption of imports of food from abroad on something like the old scale and at something like the old prices. Only in such circumstances can it be ended, unless some other radical change comes to the rescue. If the loss of our foreign assets and the fading prospects of the export drive preclude such possibilities, we are thrown back on our own resources. What hope is there then of dispensing with the subsidies, and so freeing the Exchequer of a burden which is throttling incentive all along the line ?

Fortunately there is in progress another radical change which holds out hope and which might offer the basis for a rational policy—which may, indeed, over a decade or so, bring the cost of food-production at home into line with the level of prices that the consumer can be asked to pay. Great technical advances are being made in agriculture. One has only to list the implications of the biological and biochemical sciences to realise their immense potentialities. The still new science of genetics as applied to plant life and seed-production is in its infancy. The work of Sir George Stapledon and others in the improvement of grass has yet to revolutionise the produce of our marginal land. Artificial insemination of livestock is being developed with great rapidity. The work on the control of virus diseases and insect pests being done at Rothamsted and elsewhere is likely to result in a dramatic increase in the yield of our fields. These possibilities are not far-fetched and idle dreams.

How then does this prospect affect the food subsidies ? Surely, within a fairly long period, say ten years, we may reasonably expect the cost of food-production to have been markedly reduced—perhaps sufficiently to offset the increases in the reward to the farmer now needed to step up our agriculture.

A DOUBLE POLICY

Some attempt, however tentative, to suggest the shape of a positive programme seems to be called for. A double policy seems to be indicated. First, an immediate and substantial increase in the subsidies for home-produced food for the next two or three years, to carry us over the immediate period of transition—designed to bring the maximum effect in increased production. They should not, for instance, be frittered away in petty reliefs to the consumer such as the recent reduction in the cost of the weekly ration of cheese from 1½*d.* to 1¼*d.*). Secondly, a progressive scaling-down of the subsidies by something like 10–15% per annum over the next eight or ten years, designed to give the community the advantage of the technical progress in agricultural methods. Let the subsidies rise to a total of some £500 million for say the next two years, and thereafter decline over the following decade by some £50 million per annum. It is a heavy burden on the Exchequer, and some saving may be possible on the side of the bill which relates to imported food. But at least such a programme offers the prospect of a steady lightening of the burden.

For the policy to be successful a closer integration between the Ministries of Food and Agriculture seems to be essential. In our present circumstances it may be necessary that the Minister of Food should tour America buying up what he can; but in the longer run it will be necessary to see that control of imports is vested in the Ministry responsible for the control of prices of home-grown food. Internally, too, there is room for study of the effects of subsidies upon production, since much of the subsidy money is now poured away irrespective of its uneconomic effects in encouraging production unsuited to the locality. The system is too simple; the pattern of food-production, on the other hand, is complicated, and there are subtle inter-regional relationships which a simple flat-rate system brushes aside. If the subsidies have come to stay with us yet awhile, the improvised war-time methods must be overhauled, and the whole scheme subjected to a detailed review in which the views of the agricultural experts must prevail over the political anxieties of the Ministry of Food.

The prospect as a whole contains much that is grim. A long period must elapse before a new balance is attained, and our much-vaunted industrial expansion may meanwhile suffer some check. But it is a big canvas, and there is much in the picture besides occasion for gloom. There is a story told of Mr. Churchill in the dark days when France was crumbling in 1940. Colleagues round the Cabinet table drew long faces, and a gloomy silence settled upon the meeting as the prospect of battling on alone was examined from one angle and another. "For myself," said Mr. Churchill rising from the table, "I find it rather stimulating." This surely is the attitude we need to face a future which holds out no prospects of the continuance of imported foods purchased with the interest on our foreign investments, and which certainly involves an upheaval of many of our accepted ideas.

The end of England as a great industrial exporting country ? No; for if we continue to equate our exports with our imports of raw materials, as we did before the war, we shall still be carrying far more than our proportion of international trade.

There is in sight a better balanced community, and an end to the drift to the towns with all its dubious social consequences. For 150 years past voices have been raised to protest against the spoliation of England, and the desolation and poverty of our rural community. Is it now at long last true that we have topped the curve of the graph ? Will not the change bring with it a healthier, happier, and more independent Britain, fitted to show the world how to enjoy the benefits and at the same time to curb the consequences of the industrial revolution ?

SIGNIFICANCE OF GLYCOSURIA

SIR.—In your annotation on the incidence and significance of glycosuria (June 28) you state that "every case f glycosuria requires full investigation." Should such a course be generally adopted the laboratory services would be severely strained. I can see little to be gained by doing a glucose-tolerance test on an adult who gives history of loss of weight, polyuria, and thirst, and who n an ordinary diet excretes sugar and aceto-acetates in his urine. He is a diabetic whatever the test may show. Surely these time-consuming tests are only required n doubtful and obscure cases. Would it not have been better if your annotation had read "every case of *ymptomless* glycosuria . . ."?

W. W. WALTHER
Pathologist with charge of Diabetic Clinic.
Queen Mary's Hospital for the East End, London, E.15.

THE STUDENT AND THE ALMONER

SIR,—Dr. Beryl Harding's letter in your issue of une 21 brings the recommendations of the Goodenough eport (chapter 11) once again to the fore. Already n certain hospitals experiments in teaching by the lmoners' department are being carried out. The nstitute of Almoners is bearing in mind the development of this important function in its consideration of he almoner's work, and of training for future almoners.

Institute of Almoners, Tavistock House (North), London, W.C.1.
M. STEEL
Secretary.

NURSES FOR THE ELDERLY

SIR,—In your summary of Dr. Elliott's remarks on the ursing problem in Kent you give the population of the dministrative county as 125,000. I think it is clear that nought has been omitted from this figure which should be in the vicinity of 1,250,000. Given a population of one and a quarter million upon which to draw, the arget of 2000–3000 part-time nurses should be quite ealisable.

Presumably the main reason why the Gloucestershire scheme worked in Gloucestershire was because those n charge of it intended that it should work. At present the recruitment of part-time nurses is held up by bureaucratic inefficiency. The publicity campaign is half-hearted and the ridiculous pay anomalies make women feel that the authorities are not serious about the scheme. Thus under the scheme as at present applied a part-time nurse may be willing to work more than 30 hours a week; but in Kent she is not permitted to do so, whereas in London she may do so but will receive less money than if she had worked 30 hours! As a result many women-hours which could be got from part-time workers are not utilised though offered. This situation gives volunteers the impression that their services are not in fact urgently required and undoes the positive effect of the propaganda for more nurses. The campaign to restaff the hospitals can only be successful if it is conducted by people who are convinced of the possibility of success and who are given authority to eliminate anomalies which prejudice the success of the scheme. This may involve slight additional expenditure but this should not be a real difficulty in view of the fact that according to Dr. Elliott's report already in 1946 the Kent County Council has registered its desire to spend £580,000 on building works for hospitals and institutions for the chronic sick—a sum of which only a fraction can have been spent to date.

Unfortunately, although our hospitals have at last been divorced from the poor-law, the poor-law attitude of mind is still with us.

St. Mary Cray, Kent. BRIAN H. KIRMAN.

***We are obliged to Dr. Kirman for drawing attention to our error.—ED. L.

SIR,—May I make the following comments on your annotation of June 28?

1. I feel your statement that the recruitment of some 2000–3000 part-time nurses out of a population of 125,000 is not an outrageous figure is going to mislead a very large number of people who do not know what the facts are. Our population at mid-1946 was 1,380,310; but even so, after a three-months campaign, we have managed to recruit only about 150 part-time nurses, making a total of 207. These nurses are recruited to the service of the public-health and public-assistance committees and only a proportion are, of course, available for the chronic sick. The campaign was discussed in detail with the nursing administrators and with representatives of the Ministries of Health and Labour. We also studied the Gloucestershire scheme on the spot. Nothing has been left out that was suggested to us. Incidentally, I think it is time that greater regard was had to the fact that these part-time schemes are all very well so long as other authorities are prepared to train assistant nurses, but it is useless to continue to expect any scheme of part-time nursing to meet future needs without making adequate provisions for training. Otherwise we are merely "scraping the barrel" and our future will be worse than our present.

2. I agree with everything you say about the need for a high standard of nursing for the chronic sick: but, when there are said to be 89,000 vacancies in London and S.E. England for female labour, I feel I must ask where these nurses are coming from to nurse the elderly sick. I welcome everything you have written about improving the lot of these unfortunate patients, but in spite of all that is done in Middlesex I understand that they still have a waiting-list for these patients which may be as long as ours. Our list is now 823 and there are urgent cases in front of me from which I would quote the following descriptions: "revoltingly filthy," "lying in her own fæces." The point which I think is forgotten is that these patients are not lying in their beds being cared for, but are all too frequently living in the most appalling conditions, receiving casual attention from friends and neighbours. Possibly, similar circumstances would be revealed on examination of the Middlesex waiting-list.

While, therefore, I agree with you as to what is ideal, I believe we must face the fact, or what I regard as a fact, that there are not enough women in the country to provide the ideal service that you postulate, and that in present conditions—which I do not think are likely to alter—it is only by some scheme such as I have outlined that we are going to relieve the appalling hardships that are now befalling many elderly and helpless people.

With regard to the experience at the West Middlesex Hospital, I think we shall be blinding ourselves to the existence of a current evil, which needs urgent attention, if too sanguine a view is formed through overmuch emphasis being placed upon the long-term possibilities inherent in the special steps taken at selected establishments. The active treatment of cases selected as likely to respond to it should, of course, be encouraged by every possible means, but we are fast reaching a state of affairs wherein any such cases may be refused admission to chronic-sick wards as not yet representing the urgent necessity warranting immediate attention. This, I admit, is a most sorry state of affairs, but its existence is really the main fact upon which my original article attempted to focus attention. If we are to turn all our establishments into specialist chronic-sick units, as at the West Middlesex, leaving those cases clearly not able to benefit therefrom to shift as best they may—and maybe to die as quickly as possible—then, I am afraid, we are well on the way to that "deterioration of ethics" which I referred to in my original article.

3. I am sorry that you do not comment on my conclusion in the penultimate paragraph of my article that there will not be a sufficient number of young people in the community who will be available to nurse the aged sick. If my view is not true, or is unduly pessimistic, someone should be able to reply to me and tell me where the women that are needed as nurses are now working and whether these particular fields of work can and will be divested of labour at the present juncture. Nothing that I have yet seen in THE LANCET or elsewhere gives me any faith that under present conditions some scheme can be introduced which will make a sufficient labour force available to permit us to staff our empty beds and to admit our 823 patients in any reasonable period of time. That bitter fact is, to my mind, the crux of the question.

County Hall, Maidstone.
A. ELLIOTT
County Medical Officer.

Letters to the Editor

APPEARANCE OF PROTRUDED DISKS

SIR,—In common with Mr. Charnley (June 28) I was rather surprised at some of the statements about patients with protruded intervertebral disks made by Mr. Burns and Mr. Young (May 10). At the same time I am impressed by everything that these two authorities state.

With one exception all my cases have been operated on in the crouching position, which resembles that adopted by the Moslems when praying. It was not fair of the wit at a meeting of the Royal Society of Medicine to say that this position, advocated by Pridie, resembles that of a rabbit about to spring off. In this position the lumbar spine is flexed, and so it is possible that the apearances are different to those seen when the patient is operated on in the prone or semi-prone position.

In my series the common protrusion has been that which I liken either to the tip of a little finger or to half a pea. In only one case was it pedunculated. The site is almost invariably anterior to the origin of the lumbar or sacral nerve from the dural tube, and in quite a number of cases the nerve has been firmly bound down to the protrusion. Sometimes the protrusion projects upwards between the nerve and the dural tube and sometimes it is on the outer aspect. In one case there were two protrusions, one on each side of the central strong ligament, and if one had not adopted Burns's advice to remove the whole of the fifth lamina one of them would have been missed. In one solitary case the protrusion was a loose body in the complete sense of the word "loose." This patient had been manipulated by me for sciatica about four years previously, and presumably the manipulation had shot the disk substance out; when I removed it, it was lying posteriorly to the spinal cord, and he is lucky not to have had a paraplegia as a result of the manipulation. It may be thought that it is impossible so to displace a piece of intervertebral disk. I admit that this thought was in my mind until I operated on a patient in the acute stage and discovered that the nucleus pulposus had burst through not only the annulus fibrosus but also the overlying ligamentous tissue. When encountered it resembled the appearance usually found only after incising this fibrous tissue; it was teased out in one piece.

The other type of protrusion which I have encountered is that in which the whole of the posterior portion of the nucleus fibrosus is pushed backwards. This is the type where, as Burns says, a very considerable mass of tissue must be removed. In one of these cases there had been some erosion of the posteriorsurface of the body of the bone.

I would like to support Burns and Young's statement that the diagnosis in cases of lumbo-sacral pain depends on the spinal rather than the neurological signs. My localising sign is the appearance of the disk in a straightforward radiogram. The radiologists do not agree, but in my experience it is an extremely accurate indication of which disk is affected.

To those pessimists who say that not every case is cured by the operation I would urge that they make sure that the postoperative treatment has been satisfactory and that no complications have arisen during the operation. In one of my cases I damaged the dura overlying the nerve and it subsequently became adherent to the
second operation the adhesions were
oved, and at the same time the

MATISM

r. Finkenstein has
nt people living in
be singularly free
to damp and
'climate' was
outside: the
c conditions

There is a voluminous literature to show that change of climate, and particularly damp cold, predispose t rheumatic disease of certain kinds. It can also be shown that the physical state of the atmosphere in a big city may be quite unlike that outside it in the open country Yet the temperature and barometric readings may b identical. The other factors require elucidation.

Colchester. G. C. PETHER.

A RECORD LOW HÆMOGLOBIN

SIR,—A hæmoglobin level of 12% is mentioned b Dr. Karani and Dr. Szekulesz in a letter (June 7) unde the title of "a record low hæmoglobin?" May I point t a paper on ancylostoma anæmia by A. G. Biggam a myself[1] where a hæmoglobin of 10% (Sahli) is recorded Such levels are not unusual in ancylostomiasis and a quite compatible with life.

The explanation advanced at the time was that increa in blood-volume partly compensated for this extre anæmia,[2] but later M. M. Fikri and I[3] found that i Egypt the blood-volume was not increased in cases o ancylostoma anæmia.

Cairo. P. GHALIOUNGUI.

PNEUMOTHORAX AFTER THYROIDECTOMY

SIR,—The communication by Mr. B. R. Billimoria (Jun 21) opens with the statement that injury to the apica pleura is a recognised complication of thyroidectomy Is this true, or is it one of those statements which hav appeared in textbooks and have been copied withou question?

The greatly enlarged thyroid is common in this are of England, and in operating on over 450 goitres I hav found that about 1 in 5 has some extension below th clavicle or sternum. There is never any difficulty i freeing the enlarged lower pole as the areolar tissu is fine and soft; a gentle sweep with the finger combine with traction from above is usually sufficient, and I doubt if this is likely to damage Sibson's fascia. I thin the probable explanation of the reported case is to b found in the article by H. J. Barrie,[4] to which attentio was later drawn by A. P. M. Page.[5] Barrie showed that i is possible for bilateral pneumothorax to occur by a entering the areolar tissue in the superior mediastinu via the wound or drainage tube. It is often possible if respiration is slightly obstructed, to see the areola tissue around the great vessels fill with air, and this ca continue after the operation via the drainage tube, unless Barrie's simple remedy of covering the tube with gauze impregnated with soft paraffin is adopted The following case, which occurred in 1938, is somewhat similar to Billimoria's.

During the course of an operation under intratrachea gas-oxygen and rectal bromethol for a small goitre, weighing $2^1/_2$ oz., causing mild toxic symptoms in a young woman, cyanosis appeared and persisted despite an increase in the supply and pressure of oxygen. Bubbling in the wound was noticed, but this was considered to be due to increased inspiratory effort and it was disregarded. On her return to bed the patient's cyanosis became alarming. Dr. T. A. Hunter, of Plymouth, examined the chest and found a left pneumothorax, confirmed by X-ray examination; and when this was removed by aspiration the patient quickly recovered. Radiograms of the chest before and after operation showed healthy lung fields, and the patient is well at the present day.

There seemed to be two possible explanations at the time: injury to the pleura or rupture of an emphysematous bulla. I was quite certain that I had not injured the pleura as the dissection did not approach it. The other cause seemed unlikely because there was no recurrence after the air had been removed. On reading Barrie's communication the explanation of this nearly fatal complication seemed to me clear, and since then I have made it a routine practice to cover the wound with gauze soaked in soft paraffin.

A DOUBLE POLICY

Some attempt, however tentative, to su
of a positive programme seems to be

the fact that two years after the end of the war everybody was suffering from the effects of strain. He therefore asked for an extension of food for certain classes of heavy workers, and that more should be done to see that all children entitled to priority milk actually received it. He also hoped that the age-limit for priority eggs could be extended beyond two years. Anyone who had travelled extensively, Dr. Guest thought, could say that, with the exception of the United States of America and Canada, every country had a lower standard of food than we had. Child and maternal health statistics and the general health and vigour of the country showed that we were now probably better fed than we were in the inter-war period and much better fed than we were at the end of the last war.

Dr. BARNET STROSS suggested that as we were at present consuming in our tea ration three times the maximum dose of caffeine, a little diminution by way of drinking more water or even beer would not do us any harm. The food problem was a world problem, he continued, and ours was only part of it. If our meat supplies were down by 9%, Europe was short by 40%. We must refuse to be misled by the importance of calories alone; obviously it was quality that counted. The reason why our national health had improved was that we had been compelled to eat less animal protein, and we were therefore eating more summer fruit and leafy green vegetables, despite the high prices. Recently we had been consuming more liquid milk and the quality of our fats was much better, because the vitaminisation of margarine gave great protective value, and was better than normal butter today—though he admitted he preferred butter, for the tyranny of the palate is not easily overcome. The use of wholemeal grain and a greater consumption of potatoes meant that our diet today was healthier, even though it was not fuller and was obviously more monotonous.

Lieut.-Colonel W. ELLIOT declared that the Minister of Food had explained his schemes, but at the back of everyone's mind was a haunting fear how long finance for them would continue. The dollars would run out before Christmas and there would be a gap to be closed. Full employment had already brought the consumption of this country above the point at which full activity could be maintained. Colonel Elliot agreed that our health record had been excellent, but we must remember that these figures reflected the physical condition but not the energy output of the people. The whole nation was working on a too narrow surplus of energy intake over output and found difficulty in putting out the long and sustained effort on which the future of the country depends.

Dr. E. SUMMERSKILL, in reply, said that the only valid criticism which emerged from the debate was that there was a world shortage of food. Our standard compared favourably with most European countries, for full shop windows were no real indication of the standard of living of the masses. The only method of arriving at a valid conclusion was by examining a country's rationing system to priority and non-priority consumers, ascertaining whether it was functioning effectively, and discovering the extent of the black market. We should be proud that in Britain these things could stand inspection, although she did not claim that our methods were perfect. The Ministry recognised that there were certain vulnerable groups which needed special rations, and they had done their best to distribute rations as fairly as possible among those sections which were thought to need them most.

QUESTION TIME

Administrative Machinery for the Act

Replying to a question, Mr. A. BEVAN made the following statement: Section 22 (4) of the National Health Service Act, 1946, enables me to make regulations requiring local health authorities of counties in which schemes of divisional administration are in force under the Education Act, 1944, to make corresponding schemes of divisional administration with respect to the care of children under five. My object in seeking that power from Parliament was to safeguard continuity in the health services for children. On careful re-examination I have come to the conclusion that the making of regulations would entail disadvantages, and that continuity in the health services for children can be secured, and secured more adequately and efficiently, in another way.

There would be disadvantages for two reasons. In the first place many of the areas of divisional administration, which have naturally been selected by reference to educational considerations, are not so well adapted to the administration of health services. Secondly, the arrangements for infant care under section 22 cannot, without loss of efficiency, be separately administered from the arrangements for the care of expectant and nursing mothers or from those concerned with infant health, like health visiting and vaccination and immunisation.

I believe that continuity and the maintenance, which is so desirable, of local interest can best be secured by subdividing all counties (except those where, either on account of the small size of the county or of other local considerations, decentralised administration for the whole or part of the county would be inappropriate) according to local health requirements. In each subdivision the county health committee would use its powers under the Act to appoint a subcommittee on which the councils of county districts comprising the subdivision would be represented, and to which would be delegated the day-to-day administration in the division, not only of the child care services specified in section 22 (4) but also of other services under part III of the Act. Under the county medical officer, executive charge of those services in the division will normally be taken either by an existing assistant county medical officer, preferably one who is also M.O.H. of one or more of the districts constituting the division, or by the M.O.H. of one of those districts who would be appointed to the staff of the county medical officer. There is, moreover, a limited number of non-county boroughs and large urban districts which, besides being " excepted districts " under the Education Act, house an unusually high proportion of the total population of the county, and possess exceptionally well-developed public health (including school health) services. Such a borough or urban district would ordinarily become an area of health administration separate from the surrounding districts, and the county health committee would in these cases appoint, for that borough or urban district, a subcommittee of which half or more of the members would be members of the borough or urban district council, and to which day-to-day administration would similarly be delegated. The M.O.H. of the borough or urban district would then be appointed, by agreement with the borough or urban district council, in a part-time capacity to the county medical officer's staff. Both in these areas and in the subdivisions which I mentioned earlier the county council as local health authority would retain, unimpaired, its responsibility for policy and finance.

I have consulted the associations of local authorities on this proposal, and they have informed me that they are in agreement with the principle on which it is based. I do not, therefore, intend to exercise my powers to make regulations under section 22 (4) of the Act.

Sir HENRY MORRIS-JONES asked the Minister of Health what was the present position in regard to the various bodies, lay and medical, which were to be set up under the terms of the National Health Service Act, 1946.—Mr. A. BEVAN replied: The 14 regional hospital boards have been constituted by an order which contains the names of the members, and it will be for the boards themselves in due course to appoint hospital management committees. The designation of teaching hospitals is at present under consideration, after which the boards of governors of those hospitals will be constituted. About 60 executive councils have so far been constituted, and their appointment is being announced locally. Local medical and pharmaceutical committees have been provisionally recognised in all areas, and local dental committees in practically all, but I have not the names of the members of all these bodies. The arrangements for the appointment of ophthalmic services committees, the Tribunal, the Medical Practices Committee, and the Dental Estimates Board are under consideration. On the establishment of health committees by local health authorities, I would refer to the reply given on June 26.[1] Suggestions are under consideration for appointments to the Central Health Services Council, which will in due course be consulted on the constitution of standing advisory committees.

Tuberculosis in the Army

Mr. H. USBORNE asked the Secretary of State for War how many men had been discharged from the Army, suffering

Parliament

ON THE FLOOR OF THE HOUSE

Mr. Dalton's statement on the import programme set the tone of debates for the week. The Government are maintaining food imports at the same level as last year, but there is the possibility of cuts. On Tuesday Mr. Strachey was accused, unfairly as it seemed, of using the technique of his famous R.A.F. broadcasts in the different sphere of food. Many Opposition members are revelling in gloom, and in a debate on shortages one Conservative M.P. almost prophesied the end of the England we know because we have sunk into an abyss of economic disaster. This was a bit far-fetched even for the other gloomy Opposition M.P.'s—fresh from an excellent meal in the members' dining-room.

The food debate showed clearly that while it is just as possible to make controversy out of calories as out of economic statistics, it is probably easier to nail down the inaccuracies. Members who referred to Dr. Bicknell's recent article on *Dying England* were somewhat embarrassed when Mr. Wilfrid Roberts gave a further quotation from the article suggesting that some countries in Europe seemed to be managing better than us because they "are not under such a uniform iron control as we are, and have recovered from the war because it is healthier for two-thirds of the nation to eat well and be fit and for one-third to starve." I hasten to add that even the most extreme right wing of the Opposition is not likely to adopt this inverted type of food and health plan for presentation to the electorate.

In the debate emphasis was laid on the improved standard of health we have achieved on our restricted diet. It seems fairly generally agreed that, compared with European countries who were involved in the war, our nutrition stands high. Nor is there any doubt that this high level of food-supply will be maintained. Indeed it is possible, indeed almost probable, that the food of priority classes such as young children and nursing mothers will be improved, and special attention will be given to the diet of heavy workers. But if we want to be sure of variety in our food we shall have to increase the supply of our own home-grown fruits and vegetables. A target of 100% increase in the produce of allotments and private gardens was proposed, and the Minister was asked to give such modest private growers some little extra financial incentive to produce, and to put their produce in the village shop.

The Bevin-Bidault-Molotov conference on the Marshall hint—for there is no plan until we people in Europe make it—has broken into two parts. There is hope, however, that the Economic Commission for Europe may form a bridge, for the commission is an organ of the United Nations and the Soviet Union is part of it. Thus the United Nations again may help to achieve easier and better international coöperation and understanding.

MEDICUS, M.P.

FROM THE PRESS GALLERY

Good Housekeeping

The debate on food in the House of Commons on July 1 took place, as Mr. J. S. C. REID in opening the discussion for the Opposition pointed out, under the hadow of the Chancellor's statement that drastic measures would be necessary to close the gap between our imports and exports, and that the possibility of urther cuts in food could not be ruled out. People deserved, Mr. Reid thought, to be given the facts of the ituation without reserve or equivocation. Would Mr. Dalton's statement affect our purchases from the terling area or from soft-currency countries? Did it mean that in future we were going to refuse all offers rom hard-currency countries of foods which were neither taple foods nor raw materials for agriculture, such as eeding-stuffs?

Too many controversialists were going about, Mr. Reid continued, insisting that this was a well-fed nation. Their stand-by was that now there was equality in the ountry, but no claim could be less true. He had yet o see a survey which showed that people who did not ave access to canteens and restaurants were consuming more than 2400 calories a day. A canteen meal might represent anything from 600 to 1000 calories, and the disparity between those who ate at home and those who could use canteens and restaurants was therefore as great as between Sir John Orr's top and bottom classes. But calories told only half the story. They had received undue prominence, he suggested, because unlike quality they could be measured numerically. Weight for weight there were more calories in bread than in steak, but he did not think many people would voluntarily make the exchange. In conclusion, Mr. Reid charged Mr. Strachey with bad housekeeping, lack of foresight, and a failure to face facts.

Mr. J. STRACHEY replied that if bread had not been rationed when it was the condition of the country during the last winter would have been as grave as his critics periodically predicted. Defending bulk buying, Mr. Strachey said it was an integral and indispensable part of the general policy by which the available foodstuffs were secured and distributed equitably to the people of this country, for it would be difficult to maintain the rationing system if at one point the foodstuffs did not come into Government ownership. Bulk buying also made it possible to stabilise prices and to play our part in those irksome but beneficial systems of international allocation. *The real case, however, for* bulk buying was that it enabled us to use the long-term contract which was the best instrument at our disposal for increasing the amount of food which we could find to buy in the world.

People spoke as if the Ministry of Food were unaware of the trials and difficulties of the housewives. Actually, Mr. Strachey claimed, those difficulties were better met by the efforts of the Ministry than by any words of sympathy, however eloquent. Today British housewives had the assurance of being able to take the staple articles of food out of the shops, and for the poorer housewives that was a new assurance. He admitted it was hard that two years after the war there were still the irksomenesses of shortages and rationing systems, but the Government were determined not to remove the difficulties from a few housewives; they would only remove them when they could remove them from all.

In this country, Mr. Strachey continued, people were getting between 2880 and 2890 calories a day, which was a good deal better, as Professor Marrack had lately shown in the *Times*, than the lower-income groups received before the war. Lieut.-Colonel Elliot believed that he secured some political advantage by alleging that the figure was 2325. That, said Mr. Strachey, was what the figure would be if no-one ate in catering establishments. Using this completely false figure Colonel Elliot alleged that the nation was gravely undernourished and less cautious supporters alleged that the nation was starving to death. This figure of 2325 came from the National Food Survey which had been in operation long before Mr. Strachey came into office. Their comparable figure in 1941 was 2360; for 1942 it was 2253 and for 1943 it was 2315. So they reached the inescapable conclusion that if we were slowly starving to death today we were starving to death a little more quickly when Lord Woolton was minister of food. According to calculations based on the Orr report the average level for the whole population before the war was 2275 calories. Mr. Strachey did not suggest that 2890 was a highly satisfactory level, but it was a good level in comparison with previous periods. He did not believe in a dead level of food intake for all; but at any rate the difference in intake today was largely according to need, instead of according to class.

Summing-up, Mr. Strachey said that there was no food crisis and there would be none between now and the next harvest. We had stocks of sufficient supplies in the major foodstuffs to see us through until the fruits of the 1947 northern hemisphere harvest were gathered. Looking still further ahead there was no need whatever for the people of this country to feel that they would find it difficult or impossible to obtain, partly from at home and partly from abroad, the food which they needed.

In the debate Dr. HADEN GUEST said that supposing next winter was as bad as the last, how would the Government fortify the health of the people? One of the principal difficulties at present, he thought, was not food, which he considered to be extremely good, but pneumonia (primary or influenzal), 342; cerebrospinal fever, 57; poliomyelitis, 56; polioencephalitis, 11; encephalitis lethargica, 2; dysentery, 66; puerperal pyrexia, 94; ophthalmia neonatorum, 62. No case of cholera, plague, or typhus was notified during the week.

Both cases of smallpox were notified in Staffordshire—one at Bilston and the other at Willenhall.

Deaths.—In 126 great towns there were no deaths from enteric fever, scarlet fever, or diphtheria, 7 (0) from measles, 9 (4) from whooping-cough, 76 (8) from diarrhœa and enteritis under two years, and 7 (1) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 272 (corresponding to a rate of 29 per thousand total births), including 27 in London.

Obituary

WILLIAM GOUGH

M.B. LOND., F.R.C.S., F.R.C.O.G.

Mr. William Gough, emeritus professor of obstetrics and gynæcology in the University of Leeds, died on June 29 at the age of 71. He received his medical education at Leeds, and after taking his M.B. Lond. with honours and a gold medal in physiology in 1900 he was appointed senior house-surgeon at the Leeds General Infirmary and later senior resident anæsthetist to the Women and Children's Hospital there. Settling in consultant practice in Leeds he took his F.R.C.S. in 1903, and in due course was elected to the staffs of the Infirmary and the Women and Children's Hospital. He also served as honorary medical officer to the Leeds Maternity Hospital. At first lecturer in gynæcology in the university he was later appointed to the chair from which he retired in 1936. Always greatly interested in pathology, he ran the Yorkshire Pathological Laboratory for several years. A foundation member of the Royal College of Obstetricians and Gynæcologists he was appointed to the council in 1937, and during the blitz he came to London regularly to attend its meetings. He was elected a vice-president in 1942, and in 1944 did valuable work as chairman of the examination committee.

"Gough's bent," writes a colleague, "was more towards gynæcology than obstetrics. He had an excellent general surgical training and was an exceptionally rapid and skilful surgeon. Completely ambidextrous in his surgical work, he used knife or needle equally well with either hand. He resented perhaps more than most the arduousness of obstetrics, and he was a very conservative exponent of the obstetric art. Bedside teaching did not appeal to him, but it was possible to learn a great deal from him by watching him at work in the theatre. He said little, but when he spoke it was to the point. An astute clinician with excellent judgment, he was strikingly fair-minded."

In 1905 he married Miss Agnes Innes Crane Fraser, and she survives him with one son and four daughters.

WILLIAM FIELDING ADDEY

M.D. LOND., F.R.C.P.

Dr. W. F. Addey, consulting physician to the East Suffolk and Ipswich Hospital, died at his home at Otley on June 20. Between his schooldays in Manchester and his student days in London he spent some years on the Continent, where he learned to speak German and French fluently. He took the Conjoint qualification from University College Hospital in 1899 and graduated M.B. with honours in medicine the following year. After holding house-appointments at his own hospital and at Queen Charlotte's he took his M.D. in 1902. For a time he acted as assistant surgeon at Croydon General Hospital, while practising with a group of doctors headed by Dr. Parsons-Smith. But on his demobilisation in 1919 after two years' service with the R.A.M.C. he settled in practice at Ipswich. He was specially interested in electrocardiography, and his published work included papers on heart-block and the treatment of heart disease. In 1935 he was elected F.R.C.P.

A colleague writes: "Addey was a physician of the old school, who relied chiefly on his clinical acumen and a routine investigation for his diagnosis, but he was always ready to make use of modern aids. Active in all he did, his hobbies were yachting, music, and travelling, and his keen sense of humour and charming Victorian manner endeared him to all. His mortification was great when his beloved Paris fell, and the war years took a heavy toll, so that it was no surprise when three years ago he was obliged to give up work. After a gallant struggle, followed by a long and tiresome convalescence, successfully overcome, he hoped to carry on again, but it was not to be. He died suddenly and peacefully reading a book, and his picturesque figure will no longer grace our meetings."

His widow survives him with two daughters. He was 75 years of age.

HERBERT HENRY MILLS

M.D. LOND.

When the Insurance Act was introduced Dr. Herbert Mills was one of the few who from the first took an active part to secure its working, and in his book *Politics from Within* Lord Addison writes:

> "In the struggle to which we were committed two men, Dr. H. H. Mills of Kensington, and Dr. Lauriston Shaw, one of the physicians of Guy's Hospital, stand out in my recollection as prominent for courage and ability. The opposition and opprobrium which these high-minded men endured, although they were by no means alone in this respect, was shameful and discreditable to the last degree. If ever men deserved well both of the profession and the public these two did. Their endeavour was to prevent the profession being committed, with all the misfortunes to itself and to the public that would certainly have ensued, to a refusal to coöperate with the State in a great endeavour."

Dr. Mills himself went on the panel, to the great surprise of most of his Kensington patients, and served on the advisory council of the National Insurance Act, and the London Insurance Committee. He was elected president of the West London Medico-Chirurgical Society in 1931, and was also a fellow and member of the council of the Medical Society of London, a member of the council of the Röntgen Society, and a medical referee for the Prudential and other insurance societies.

Dr. Mills, who had qualified from the Westminster Hospital in 1891, continued practising until three days before his death on July 1, at the age of 78, from pneumonia and heart-failure. He leaves a widow and one daughter, Dr. Hermia Mills.

FRANCIS ELLIOT FOX

B.A. CAMB., M.R.C.S.

Dr. Fox, who died on April 27, was medical superintendent of Brislington House, Bristol, a private mental hospital which has been owned and administered by his family for several generations. His father, Dr. Bonville Fox, died when he was a boy, and the succession from father to son was further delayed by service in the 1914–18 war. On leaving Winchester F. E. Fox joined the Army, where he reached the rank of captain. While stationed in Persia towards the end of the war he received grave head injuries, but he made a good recovery and was able in 1919 to go up to Cambridge to begin the study of medicine. From Caius College he went to the London Hospital and qualified in 1924. After holding a clinical assistantship at the London and a house-appointment at the Bethlem Royal Hospital, he was for a time assistant medical officer at Peckham House before he returned to Bristol to take up the work for which he had trained. In 1940 he published in the *British Medical Journal* a paper describing his clinical experience with electrically induced convulsions.

A man of fine presence and kindly bearing, "Sonny" Fox (as he was affectionately called by his many friends) was capable both in professional and public affairs. He was a member of the Bristol city council and for many years chairman of the Frome Conservative and Unionist Association. His chief hobby was gardening, and at Brislington House he made a beautiful garden even more beautiful. He married in 1940 Ethel Mary Skuse, who survives him with one son.

from tuberculosis, between September, 1939, and June, 1945; and June, 1945, and the present time, respectively.—Mr. F. J. BELLENGER replied: The figures are as follows:

	Pulmonary	Other sites	Total
September, 1939, to June, 1945 (inclusive)	16,625	3103	19,728
July, 1945, to April, 1947 (inclusive) ..	4114	549	4663

Egg Priority for Children

Dr. HADEN GUEST asked the Minister of Food what were the present arrangements for supplying eggs to children up to two years of age; and how many eggs were supplied per child for the months of October, November, and December, 1946.—Dr. SUMMERSKILL replied: Children between the ages of six months and two years receive a priority supply of eggs at the rate of three a week, and all other children receive one egg at each ordinary allocation. During the last three months of 1946 each child in the priority class received approximately thirty-nine eggs, and other children received approximately eight eggs each.

Future Level of the Meat Ration

Colonel A. WIGG asked the Minister of Food if he was yet able to make a statement about the future level of the meat ration.—Dr. SUMMERSKILL replied: It will, unfortunately, be necessary to reduce the canned corned meat ration from 4*d.* to 2*d.*, thus returning to 1*s.* 2*d.* total meat ration from July 13. When the meat ration was raised to 1*s.* 4*d.* last July, the Minister said he hoped that it could be kept at that level throughout 1946, and possibly into the early months of 1947. We have, in fact, maintained the 1*s.* 4*d.* ration for 6½ months of this year. The reasons that it has now to be reduced are, primarily, the falling home production caused by this year's severe weather and heavy slaughtering last autumn, and a temporary factor, the abnormal growth of feed in recent weeks, which has led farmers to delay the sale of fatstock until later in the year. If home supplies had been normal we should have been able to raise the carcase meat ration by 2*d.* when we reduced the canned corned meat ration—which we always knew we should have to do sometime this year. It is impossible to say at present how long the ration will have to remain at 1*s.* 2*d.*, nor how much of it will have to be issued as canned corned meat; the position is bound to be difficult for several months. The House may be assured, however, that we shall make the most determined efforts to restore it to 1*s.* 4*d.*

Rehabilitation of ex-Service Pensioners

Mr. H. HUGHES asked the Secretary of State for Scotland how many rehabilitation centres for members of the Forces there were in Scotland; where they were situated; and if he would make a statement on their work and progress.—Mr. WESTWOOD replied: Provision is made by the Ministry of Pensions for the medical rehabilitation of ex-Service pensioners at their hospital in Musselburgh, and the Ministry also have arrangements for the treatment of ex-Service pensioners at a hospital in Glasgow where similar provision exists. I understand that all patients in the Ministry's hospital whose physical condition permits undergo a course of medical rehabilitation in a fully equipped centre as part of routine treatment and that very satisfactory results have been achieved. I am also informed that the Ministry of Labour and National Service are taking steps to establish a centre near Glasgow for industrial rehabilitation at which special provision will be made for ex-Servicemen.

Death Certificates

Mr. J. A. SPARKS asked the Minister what precautions were taken to secure that the cause of death certified upon a death certificate was correct; and, in view of the evidence at the recent coroner's trial at Southport, what steps he proposed to take to ensure that death should not be certified from wrong or false causes.

Wing-Commander N. J. HULBERT asked the Minister if he was aware that the law now permitted medical practitioners to issue death certificates in respect of near relatives; and if he proposed to introduce legislation to amend this practice.—Mr. BEVAN replied: The position under the Births and Deaths Registration Acts and Regulations is that a registered medical practitioner who is otherwise competent in the circumstances of the particular case to give a certificate of the cause of death is not precluded from doing so by reason of relationship to the deceased, and it is not open to the registrar of births and deaths to reject a certificate on that ground. The duties of the registrar include the duty to report to the coroner before registration deaths in certain specified categories including any which he has reason to believe to be unnatural, or accidental, or attended by suspicious circumstances, or the cause of which appears to be unknown. I do not at p contemplate amending legislation on any of these matters.

Mr. H. HUGHES: Will the Minister consider introducing a provision whereby death certificates shall be countersigned by an independent medical practitioner?—Mr. BEVAN: I do not contemplate any amendment of the law at present.

School Meals and Milk

Mr. S. SWINGLER asked the Minister of Education how many gallons of milk per month were distributed to, and how many meals per day were served in, schools in England and Wales during the first quarter of 1947, by comparison with the same quarter of 1939.—Mr. TOMLINSON replied: I regret that comparable quarterly figures are not available, and that the returns obtained in February, 1947, were rendered unreliable by the severe weather. For the year 1946 the monthly consumption of school milk averaged 3,54[illegible] gallons, including the consumption at the independent schools, which were admitted to the scheme in 1942. The average monthly consumption in the year preceding the war was approximately 2,250,000 gallons. The daily number of children having dinner at grant-aided schools in October, 1946, was 2,252,000, and the corresponding figure in 19[illegible] before the outbreak of the war, is roughly estimated at 250,000.

Doctors' Panels

Mr. S. HASTINGS asked the Minister of Health how many doctors undertaking service under the National Health Insurance Act had approximately the maximum number on their lists; and how many within 500 of this maximum.—Mr. BEVAN replied: I regret that the desired information is not available.

Public Health

Smallpox

Barnsley.—After an interval of four weeks the sixteenth case was detected and removed to hospital on June 30; the diagnosis has been confirmed by the recovery of variola virus on egg culture. The patient is a woman, aged 62, vaccinated in infancy and during the 1914–18 war. She is suffering from a modified attack commencing on June 24, with a discrete rash appearing on June 28. The source of infection is at present undetermined.

Bilston.—A schoolboy, aged 10, was removed on July 2 as a suspected case. A rash had appeared on the previous day. He had been vaccinated on June 23. The diagnosis is still unconfirmed.

Poliomyelitis

Notifications for the week ending June 28 show a further increase to 56, compared with 44 in the previous week and 8 in the corresponding week of 1946. The disease is widely scattered over the country, some three dozen sanitary districts being involved.

Polioencephalitis

Polioencephalitis notifications have also jumped to 11 from an average of 2 to 3 a week. It is not yet known whether this rise is merely a reflection of the increased incidence of poliomyelitis or whether there is in fact a prevalence of encephalomyelitis and encephalomeningitis distinguishable from anterior poliomyelitis and resembling the series of cases described by Jennings.[1] An increase in cerebrospinal-fever notifications to 57 may have some significance in this connexion. Perhaps more information on this subject would be forthcoming if practitioners ceased to restrict notifications of polioencephalitis to cases believed to be manifestations of anterior poliomyelitis.

Infectious Disease in England and Wales

WEEK ENDED JUNE 28

Notifications.—Smallpox, 2; scarlet fever, 91[illegible]; whooping-cough, 2052; diphtheria, 182; paratyphoid, 10; typhoid, 10: measles (excluding rubella), 937[illegible] coördinating board at Ministry level could do much to promote civil-aviation medicine; one of the board's tasks would be to ensure suitable first-aid arrangements at airports.

---

[1] Jennings, G. H. *Lancet*, 1947, i, 471.

SCOTTISH EXECUTIVE COUNCILS

ORDERS made by Mr. Joseph Westwood, Secretary of State for Scotland, fix the areas to be served by the 25 executive councils which are to be set up under the National Health Service (Scotland) Act, which comes into operation next year on July 5. Glasgow, Edinburgh, Dundee, and Aberdeen are each to have their own council, as are the counties of Angus, Ayr, Caithness, Dumfries, Dunbarton, Fife, Inverness, Lanark, Orkney, Renfrew, Ross and Cromarty, Sutherland, and Zetland. The remaining twenty counties are grouped under 8 executive councils, the combinations being Aberdeen and Kincardine; Argyll and Bute; Banff, Moray, and Nairn; Kirkcudbright and Wigtown; Midlothian, West Lothian, East Lothian, and Peebles; Perth and Kinross; Roxburgh, Berwick, and Selkirk; Stirling and Clackmannan. According to the Department of Health for Scotland appointments to the councils will be made in a few weeks' time. Members are to be appointed partly by the local authorities and the doctors, dentists, and chemists in each area, and partly by the Secretary of State. The councils are to be responsible for administering the family-doctor service and dental services for the general public, and for arranging for pharmaceutical supplies in connexion with both medical and dental treatment.

University of Cambridge

On June 17 the degree of M.D. was conferred on M. S. M. Fordham.

University of London

Mr. D. W. Logan, D.PHIL., has been appointed principal of the university in succession to Mr. Harold Claughton, who is retiring at the end of the year. Dr. Logan has been clerk of the university court since 1944.

University of Birmingham

On July 4 the degree of M.D. was conferred ex officio on Prof. William Melville Arnott, Prof. Thomas McKeown, and Prof. J. M. Smellie, and the degrees of M.B., CH.B. on Dr. J. J. Elkes. The following degrees and diplomas were also conferred:

M.B., Ch.B.—M. G. FitzGerald (with second-class honours); J. W. Baker, J. B. Binks, C. W. Bird, D. G. Boyle, F. A. J. Bridgwater, Philippa H. Cadbury, A. E. Caines, A. M. Clark, C. P. Cotterill, G. A. Dalton, Deryk Darlington, C. J. C. Davey, Jean M. Evans, Sheila Fairclough, Margaret L. Fallon, G. E. Faulkner, O. P. Gray, D. A. Hanson, F. G. Isaacs, W. C. Lees, W. H. McIlveen, Beryl W. Marson, F. W. Millard, A. L. Mintz, J. C. E. Pougher, L. W. Robinson, P. W. H. Robinson, Barbara Shaw, N. K. Shinton, M. J. Simpkiss, Geoffrey Slaney, A. J. White, Rose A. J. Whitelaw, Margaret D. Wigley, *Jacqueline Domenet, *Ruth W. Towler.

D.P.H.—Edith M. M. Alexander, Joyce M. Allen, R. J. Calvert, Frances M. Earle, Herbert Geuter, J. R. Gibson, D. M. I. Harmar, A. F. Morgan, E. C. Ostler, W. R. Perry, R. G. Record, B. D. Robinson, F. A. Smith, Margaret M. Timpany.

C.P.H.—T. F. H. Duffell, F. E. Fletcher, Evan Williams.

* In absentia

University of Durham

At congregations held on July 1 and 2 the following degrees were conferred:

M.D.—P. B. Crone, W. A. S. Falla, *J. H. Middlemiss, Charles Neubauer, *S. G. Siddle, *Paul Szekely, Mary D. Taylor.

Ph.D. (in Medicine).—*Shujaat Ali.

M.B., B.S.—J. P. Anderson, Anthony Ashcroft, G. M. Bell, *S. A. Biggart, Joan Bride, Sheila M. Cameron, D. J. Cawthorne, Lucy E. Coates, Rowland Cowley, Jacqueline Elliott, L. H. Field, Peggy Foster, J. B. Fox, Jan Glaser, D. L. Golightly, A. C. Griffith, W. P. Haigh, Anthony Hand, Bernard Hayes, Catherine V. Johnston, Jessel Josephs, A. R. Kirby, H. F. Lake, T. K. Lamballe, *D. B. Leaming, Elizabeth U. Lee, M. F. Levy, F. I. Locke, Lorna M. McLeod, *Keith McKay, Margaret A. Nattrass, A. O. Odulate, Margaret J. Parbrook, *R. T. Parr, David Refson, A. A. Reid, M. C. Robson, A. L. Rowe, J. N. S. Simpson, Patricia M. M. Smith, A. H. Snaith, *W. E. Suffield, Sonia H. J. Sumner, Evelyn Swangren, Anastasia Swinburne, Helena C. W. Wardle, D. G. V. Whittingham.

* In absentia.

University of Dublin

On July 2 the following degrees were conferred at the School of Physic, Trinity College:

M.D.—W. P. Griffin, Philip Jabkovitz, H. D. McGorry, L. L. Nel, A. E. B. de Courcy Wheeler.

M.Ch.—G. E. Nevill.

M.B., B.Ch., B.A.O.—H. A. Adams, A. D. H. Browne, C. R. Deuchar, Marion T. Gaston, M. V. Graham, E. R. Haynes, Evelyn M. Holberton, Monica A. Jackson, A. J. F. Kilpatrick, Fenwick Kirkpatrick, G. B. Leitch, E. A. McColl, J. M. McCormick, R. M. Peet, Marjory A. Pollock, M. S. Strong, Elizabeth M. Wann, Ruth R. Watson, J. L. Wilkinson, Ian Wilson.

University of Manchester

At recent examinations the following were successful:

M.D.—S. B. Rampling.

M.B., Ch.B.—P. D. Fowler, Muriel Lister, Letitia E. Woodvine (with second-class honours); Barbara Anderson, Margaret Bagshaw, Mary L. Barrett, Kurt Benger, J. I. Bentley, Peter Brooks, D. L. Chadwick, Elizabeth H. Clow, Sheila A. Costello, P. J. Croxford, Leslie Dawson, Jack Dubberley, R. D. P. Eaton, George Fairclough, Maurice Feingold, J. R. C. Flett, S. F. Gilbert, Ruth Goodier, Bernard Goodman, K. S. Holt, Christine M. Hope, Thelma B. Hoyle, A. K. Karfoot, D. P. Keirby, N. P. Lancaster, William Lees, D. C. Lindars, G. P. Love, H. G. Lowe, V. T. Mason, J. G. Mathie, H. L. Matthews, I. O. Miller, G. N. L. Mulliner, Alan Murphy, Jack Nagington, J. A. Nightingale, L. M. Norburn, John Rimington, S. L. Royce, Margaret E. R. Stoneman, D. B. Stott, C. H. Thompson, J. T. L. Unsworth, G. W. Waters.

D.P.M.—H. A. Cole, Robert Cotter, R. C. Cunningham, Samuel Falk, I. McD. Kerr, M. G. McColl.

University of Aberdeen

On July 3 the following degree and diplomas were conferred:

M.D.—L. D. M. Gavin.

D.P.H.—James Cramond, Alma C. Dickie, J. L. T. Dickie, J. S. Hamilton, R. B. Killoh, A. W. McBain, Robert McDonald, Alexander Mair, W. H. P. Minto, R. G. Murray, G. M. Reid, G. S. Riddell, A. G. Scott, E. T. Shennan, A. A. Shivas, W. D. Swinney, W. L. Walker, J. H. Wood.

University of Glasgow

Dr. J. N. Davidson has been appointed to the Gardiner chair of physiological chemistry in the university in succession to Prof. G. M. Wishart, who has been appointed director of postgraduate medical education in the university. Professor Davidson has held the chair of biochemistry in the University of London at St. Thomas's Hospital medical school since last year.

Royal College of Surgeons of England

Election to the Council.—On July 3 Mr. R. J. McNeill Love was re-elected and Mr. A. Lawrence Abel and Mr. J. B. Oldham were elected members of the council. Sir James Walton, who also received the requisite number of votes, is prevented by the terms of the 1947 charter from taking his seat as he has already served for 16 years. There will, therefore, be a vacancy until the next election. The result of the poll was as follows:

	Votes
R. J. McNEILL LOVE (Royal Northern)	839
[SIR JAMES WALTON (London)	835]
A. LAWRENCE ABEL (Princess Beatrice)	637
J. B. OLDHAM (Royal Liverpool United)	629
A. DICKSON WRIGHT (St. Mary's)	609
H. W. SYMONS (General Infirmary, Leeds)	557
H. C. EDWARDS (King's College)	478
L. CARNAC RIVETT (Middlesex)	356
M. F. NICHOLLS (St George's)	277

In all 1563 fellows voted: in addition 6 votes were found to be invalid.

King's Physicians

The King has appointed the following to be his honorary physicians for a period of three years:

Dr. James Boyd, chief M.O., ministry of health and local government and ministry of labour, Northern Ireland; Sir Allen Daley, M.O.H. and school M.O., London County Council; Dr. A. M. Fraser, M.O.H., Inverness (Highlands and Islands Medical Service); Sir Walter Haward, D.G.M.S., Ministry of Pensions; Sir Wilson Jameson, chief M.O., Ministry of Health and Ministry of Education; Dr. Norman Tattersall, P.M.O., Welsh National Memorial Association.

Royal Society of Medicine

Colyer Prize.—Applications for the next award of this prize should be submitted not later than Oct. 1, 1947, to the prize committee at 1, Wimpole Street, London, W.1. The award is offered for the best original work in dental science completed during the previous five years by a dental surgeon educated at any recognised dental school in Great Britain or Northern Ireland, who has not been qualified for more than five years.

Petrol Rationing Periods

The Ministry of Fuel and Power have decided to extend from four months to six months the rationing periods for supplementary allowances of petrol for private cars and certain other vehicles. For medical practitioners the next rationing period will cover the six months from Oct. 1, 1947, to March 31, 1948. This will be made clear in a printed letter which will accompany the issue of coupons in September. The change has been made for the convenience of business and professional car users and to secure staff savings in the regional petroleum offices. It does not mean that in future a four months' allowance will have to last for six months.

Appointments

BLACKWOOD, WILLIAM, M.B. Edin., F.R.C.S.E.: asst. pathologist, National Hospital for Nervous Diseases, Queen Square, London.

DOBBIN, MURIEL, M.B. Glasg.: M.O. for maternity and child welfare, Bermondsey.

GIBSON, G. H., M.B. Glasg., D.P.H.: deputy county M.O.H., Leicestershire.

HALPERIN, RACHEL, M.B. Lond., D.P.H.: deputy M.O.H., Guildford.

JAY, J. W. W., M.R.C.S.: asst. radiologist, Bradford Joint Hospitals Council.

KIPLING, M. D., M.R.C.S., D.T.M. & H.: asst. port M.O., Liverpool.

PHILPS, F. R., M.B. Lond.: asst. county M.O., Salop.

PICCIOTTO, L. G., M.R.C.P., D.M.R.: asst. radiotherapist, Mount Vernon Hospital and the Radium Institute, Northwood, Middlesex.

REES, HARLAND, B.M. Oxfd, F.R.C.S.: surgeon, St. Peter's Hospital for Stone, London.

RICKARDS, A. G., M.B. Lpool: pathologist, Royal Lancaster Infirmary.

SHILLITOE, A. J., M.B. Lond., M.R.C.P.: pathologist, Kingston-upon-Hull health department.

VARLEY, J. F., M.B. Camb., M.R.C.P.: physician, Southlands Hospital, Sussex.

WHETNALL, EDITH, M.S. Lond., F.R.C.S.: director of deafness aid clinic, The Royal National Throat, Nose, and Ear Hospital, London.

Queen Mary's Hospital for the East End, London:

Asst. Obstetric Surgeons:

BARNS, H. H. F., M.B. Lond., F.R.C.S., M.R.C.O.G.

SPIERS, B. G., M.B. N.Z., F.R.C.S.E., M.R.C.O.G.

The Hospital for Sick Children, Great Ormond Street, London:

BONHAM CARTER, R. E., M.B. Camb., M.R.C.P.: physician to outpatients.

KEITH, DOROTHEA, M.B. Belf.: house-surgeon.

LAURANCE, B. M., M.R.C.S.: house-physician.

STREET, F. N., M.B. Sydney, F.R.C.S.: house-surgeon.

TIZARD, J. P. M., B.M. Oxfd, M.R.C.P., D.C.H.: resident medical registrar.

WINCE, W. H. D., M.B. Lond.: house-physician.

Selly Oak Hospital, Birmingham:

CLARKE, G. R., M.B. Birm., F.R.C.S.E.: chief asst. surgeon.

GUEST, I. A., M.D. Camb., M.R.C.P.: chief asst. physician.

HOBBES, T. H., M.B. Lond., D.A.: anæsthetist.

JACKSON, W. P. U., M.B. Camb., M.R.C.P.: chief asst. physician.

LEASK, A. R., F.R.C.S.: chief asst. surgeon.

MCCUTCHEON, JANE, M.B. Glasg.: resident asst. anæsthetist.

NEVILLE, MARY, M.B. N.U.I., D.OBST. R.C.O.G.: chief asst. gynæcologist and obstetrician.

PHILIP, W. M., M.B. Lond., M.R.C.P.: chief asst. physician.

WHITE, J. R. A., M.B. St. And., F.R.C.S.E.: chief asst. surgeon.

General Infirmary, Burton-on-Trent:

JOHNSTONE, R. D. C., M.D. Lond., M.R.C.P.: visiting physician.

MACMAHON, JAMES, M.B. N.U.I.: casualty officer.

West Riding, Yorks:

M.O.H. and divisional M.O.:

PROCTER, R. A. W., M.C., M.B. Camb., D.P.H., D.T.M. & H.

REEVES, A. J., M.B. Dubl., D.P.H.

Births, Marriages, and Deaths

BIRTHS

AMBROSE.—On July 1, in London, the wife of Dr. Gordon Ambrose—a daughter.

FORSYTHE.—On June 29, the wife of Dr. Kirk Forsythe—a son.

FOSTER.—On June 26, at Ryde, Isle of Wight, the wife of Surgeon Lieutenant A. O. Foster, R.N.—twin sons.

GEARY.—On July 3, in London, the wife of Dr. H. V. Geary—a daughter.

MAYNE.—On June 27, the wife of Dr. A. H. Mayne—a son.

PRIDIE.—On June 27, the wife of Mr. Kenneth Pridie, F.R.C.S.—a son.

WILSON.—On June 29, in Glasgow, the wife of Dr. R. B. Wilson—a daughter.

MARRIAGES

EVANS—MORE.—On May 31, at Ipswich, Gordon M. Hylton Evans, M.R.C.S., to Hannah Mary More, S.R.N.

ILLINGWORTH—REDHEAD.—On July 3, Ronald S. Illingworth, M.D., to Cynthia Mary Redhead, M.B.

KENNON—HUGHES.—On June 28, at Wrexham, Robert Warton Kennon, M.B., to Joan Margaret Hughes, M.B.

RYDER—RODEN.—On June 28, at Bristol, Michael H. Ryder, M.R.C.S., to Edith Stéphanie Roden.

WALTERS—LARGE.—On June 30, in London, Geoffrey Alexander Bagot Walters, F.R.C.S.E., to Daphne Large.

DEATHS

BERRIDGE.—On July 5, at Enderby, near Leicester, William Robert Morpott Berridge, M.R.C.S., aged 80.

BLAKEMORE.—On July 6, at Ipoh, Malaya, William Leslie Blakemore, M.B. Birm., D.T.M. & H., D.P.H.

CLEVERTON.—On July 2, at Bel Royal, Jersey, Thomas Charles Albert Cleverton, M.R.C.S., aged 67.

DAVIES.—On June 24, at Mooi River, Natal, William Thomas Frederick Davies, C.M.G., D.S.O., M.D. Lond., aged 86.

GOUGH.—On June 29, at Leeds, William Gough, B.SC., M.B. Lond., F.R.C.S., F.R.C.O.G., aged 71.

MACKENZIE.—On July 4, at Naze Hill, Samuel Ridley Mackenzie, M.D. McGill, aged 85.

MAYLARD.—On June 27, at Peebles, Alfred Ernest Maylard, B.S. Lond., F.R.S.E., aged 92.

MILLS.—On July 1, Herbert Henry Mills, M.D. Lond.

Notes and News

WORLD FEDERATION OF CLINICAL PATHOLOGISTS

A WORLD federation of societies devoted to clinical pathology will, it is hoped, be brought into being as the result of a meeting of the European Association of Clinical Pathologists held at Cambridge on June 27. At this meeting the European Association reconstituted itself as a World Federation of constituent bodies. Dr. S. C. Dyke, president of the European Association, occupied the chair; members of interested societies in Czechoslovakia, France, Great Britain, Norway, and the U.S.S.R. attended. The meeting appointed a committee composed of Dr. Dyke as chairman, Dr. W. H. McMenemey and Dr. J. Ungar as joint secretaries, and Dr. R. Cruickshank (London), Prof. Raoul Kourilski (Paris), and Dr. F. Pick (Prague) as advisory members, for the purpose of calling a meeting of delegates from as many interested associations as possible in Paris next November during the meeting of the French Société de Biologie Clinique, with a view to formulating a constitution and electing officers.

The aims of the World Federation will be: (1) to develop clinical pathology, defined as the application of pathology and its allied sciences to medicine; (2) to have regard to the scientific and professional status of those engaged in its study and practice; and (3) to foster international amity and goodwill. The constituent bodies composing the federation will be societies devoted to the advancement of clinical pathology. All members of such constituent bodies who are qualified medical practitioners or university graduates engaged in the study and practice of clinical pathology will ipso facto become members of the federation; in addition individual membership will be available to all who are eligible for membership but are unable to form or belong to a constituent body. It is intended that all constituent bodies shall throw their meetings open to members of all other constituent bodies, and it will be a first aim of the federation to encourage a free intermingling of its members at all meetings of the constituent bodies. It is proposed that the federation shall hold a general conference at least once in every three years at the same time and place as the summer meeting of one of its constituent bodies. It is hoped that the first conference may be held in the summer of 1948.

The Czechoslovak Association of Clinical Pathologists through its president, Prof. H. Sikl, the French Société de Biologie Clinique through Prof. R. Kourilski, and the Association of Clinical Pathologists of Great Britain through its secretary, Dr. McMenemey, have signified their readiness to join the federation. It is hoped to gain a world-wide membership, and societies throughout the world devoted to clinical pathology are invited to communicate with the joint secretaries of the federation committee: Dr. W. H. McMenemey, Pathological Department, the Royal Infirmary Worcester, or Dr. J. Ungar, Glaxo Laboratories, Greenford, Middlesex.

B.O.A.C. MEDICAL SERVICE

AN account of the medical branch of British Overseas Airways Corporation was given by Air Vice-Marshal Sir William Tyrrell, the medical director, at a press conference in London on July 8. The principal aims, he said, are safety, regularity, and comfort; and one of the first tasks is to humanise air transport. The medical service of a civil airline should be an intimate service in which the doctor has leisure to study the air-crews or ground-technicians for whom he is responsible; and the doctor must come to be regarded not as a "career-cutter" but as seeking to help air-crews to achieve their full expectation of life and to retain their economic independence. In accidents the human element is paramount; and the doctor's job should be to penetrate unobtrusively into the lives of pilots so that he can judge of their fitness to fly. Eventually the doctor may be allowed to use his intimate knowledge to stand down, in conjunction with the executive branch, any member of an air-crew, without ignominy or effects on the man's career; but this essential improvement calls for great increase in the size of the medical service. To retain their alertness flying personnel, like athletes, must discipline themselves. Sustained self-discipline of this sort is not easily achieved, and certainly regulations will not achieve it. It calls for an inspired executive and medical service and for first-class flying personnel; but it can come really only from within the individual and the corps of individuals, and for its attainment a corps d'élite spirit must be fostered. A central

THE EDUCATION OF PSYCHIATRISTS *

AUBREY LEWIS
M.D. Adelaide, F.R.C.P.
PROFESSOR OF PSYCHIATRY, LONDON UNIVERSITY

Alan Gregg recently said that the Rockefeller Foundation had spent most of its funds for psychiatric development in subsidies for the teaching of medical students and the training of young recruits to psychiatry because the recruitment, selection, and training of psychiatrists is of cardinal importance to any and every activity in this field. This, I think, is what most of us believe, but we have not acted on this belief; and if we mean now to make good training our chief immediate aim, we shall be forced to traverse some awkward country, throwing away goods that we have prized, and learning to distrust and redraw some of our time-worn maps.

The university is the institution in which higher education lives and develops. In emphasising the place of the university in the training of psychiatrists I may seem to run perversely against the tradition of clinical instruction and hospital experience, in which the university played little or no overt part; but the influence of the university, the sun of the educational system, warms and refreshes clinical teaching in psychiatry, as in other branches of medicine.

STUDENT OPINION

Who are to be taught, and to what end are they to be taught? To the first question there can be no steady answer because every year the training of medical undergraduates is changing, especially in what they learn about psychiatry; and it varies much from place to place; yet this is what decides the knowledge and outlook to be expected of new entrants into the specialty. Upon it, also, and upon the credit of psychiatry as medical students learn to judge it through their training, depends the type of man and woman who will want to enter the psychiatric field. Unless psychiatry is well taught, and the conditions for teaching it well are provided in medical schools, there can be no hope that the abler students and those best suited to study and practise psychiatry will be attracted to it sufficiently. Eloquent appeals; arguments, however useful and true; enticements, whether in the form of material prospects in pay and promotion or as alluring chances for doing good and advancing knowledge—all these will, I believe, have little (or only adverse) effect in enlisting good recruits unless medical students see for themselves during their course that psychiatry is an absorbing field of medicine, one which gains the devotion of people whom students respect and would emulate.

Though the outlook of medical students is already becoming more favourable, no doubt in response to effective teaching, it is still commonly asserted in this country that medical students form a poor opinion of psychiatry and psychiatrists. They say the same in the United States, and at Yale Professor Kahn and his associates tried to discover how things really stood, by getting their students—who had just sat their final professional examination—to answer a detailed opinion-questionary, of the multiple-choice type. I have been able, through the generous coöperation of Dr. E. B. Strauss and Dr. Henry Wilson, to obtain and analyse voluntary and anonymous replies to almost the same questionary from 75 final-year students of two large London medical schools. Like the Yale students they show a more friendly and appreciative attitude towards psychiatry than some would have expected.

That it was not only the favourably disposed who answered is shown by the replies to several questions—e.g., that which ran: "Do you intend to become a psychiatrist?" Of the 75, 26 said they had never thought of doing so and 23 more said emphatically that they strongly rejected the possibility. To the question whether they would refer a relative or friend with signs of a psychiatric disorder to a psychiatrist, 16 said they were rather uncertain whether they would or not. But in their answers to questions of a less directly personal flavour their attitude was more favourable. Rather more than half of them gave psychiatry as one of the fields (out of fifteen branches of medicine listed) in which a man going into general practice most needed to be trained; 47 would call a psychiatrist for a case of asthma that was difficult to treat; 55 liked their work with psychiatric patients; 46 considered the average psychiatrist's knowledge of general medicine adequate; 30 thought psychiatrists could be often, or very often, of assistance to physicians and surgeons in their clinical problems, and the rest (45) thought that psychiatrists could sometimes be of such assistance; 44 thought that psychiatrists on the whole had a better understanding of the life problems of the patient than had other physicians, and only 2 that psychiatrists had less understanding of such problems; 38 believed that what psychiatrists do frequently helps their patients, and 31 more believed that it is sometimes beneficial (only 4 thought it sometimes or often harmful); 11 were certain, and 41 disposed to believe, that psychiatrists have valuable techniques to teach other physicians and medical students; 31 felt fairly certain that they understood themselves better after their course in psychiatry, and 51 were disposed to say that after it they could understand the general problems of patients better.

Moreover, they were dissatisfied with the amount of clinical experience they had had in psychiatry: 61 said they had not examined enough psychiatric patients, and 35 wanted more guidance and advice in their work with such patients.

To one question, however, the answers were chastening: 22 of these keen young observers were fairly certain, and 21 others inclined to think, that there are more odd and peculiar people in psychiatry than in other medical specialties: only 2 considered there are fewer oddities in our ranks than in the other specialties. But (apart from this curious lapse in discernment) it seems safe to infer from the replies of the 75 students that psychiatry is not now a laughing-stock or a closed book to the bulk of medical students but a serious and on the whole respected branch of medicine.

THE ALL-PURPOSES PSYCHIATRIST

How are psychiatrists chosen? Selection is impossible unless there are more applicants than vacancies that must be filled. This has hardly been the case with us. Nor could we truly say that we know the qualities desirable and detectable in the fledgling psychiatrist, apart from those that we would seek for in the fledgling pædiatrician or the fledgling neurologist, or indeed in any good doctor: we could, of course, exclude some unsuitable people—stupid, immature, cruel, or leaden—but the positive goal, the ability to recognise peculiarly suitable people, is still outside our grasp. Guiding the right medical student, therefore, into psychiatry will seldom be a deliberate act by his educators, who have sized up his qualities, but often the unintentional, happy outcome of livening his interest and helping his aspirations until he catches fire and knows thenceforward that he would like most to work in one of the rooms in this rambling, rising house of psychiatry.

Since there are so many rooms, specialisation within the specialty has been urged upon us, to follow a brief common training. This is at best a premature suggestion: unfortunately it has also in some cases been our over-hasty practice; the ill effects are now constantly bothering us. Every psychiatrist, surely, must have a good all-round training; and such a programme as that proposed by the Royal College of Physicians would make this possible, so far as a programme can.

The aim of the training is an all-purposes psychiatrist. When he is asked to treat a child, to report on a criminal, to explain the origins of a strange symptom, to supervise a

---

* Presidential address to the section of psychiatry, Royal Society of Medicine, Sept. 26, 1946.

Kent Pædiatric Society

On Saturday, July 26, at 3 P.M., at the County Hospital, Farnborough, Prof. Lionel Penrose, F.R.S., will speak to this society on Genetics in Relation to Pædiatrics.

Faculty of Radiologists

At the annual general meeting of the faculty, held in Birmingham on June 27, Sir Leonard Parsons was elected an honorary fellow.

Society of Lincoln's Inn

The first Bennett prize of £100 has been awarded to Dr. A. L. Banks, a senior medical officer of the Ministry of Health, who is also a barrister of Lincoln's Inn, for his essay on the Jurisdiction of the Judicial Committee of the Privy Council.

British Empire Nurses' War Memorial Fund

The Queen attended a garden party at St. James's Palace on July 8, when she received contributions collected for this fund which has now reached a total of £45,800. The Royal College of Physicians and Viscountess Mountbatten have also each given a travelling scholarship for nurses.

Postgraduate Federation

A Royal Charter has been granted to the British Postgraduate Medical Federation of the University of London, and a supplemental charter to the British Postgraduate Medical School, Hammersmith, which will henceforth be known as the Postgraduate Medical School of London.

Oliver Memorial Fund

The trustees of this fund will make a first award of £50 to a British subject for original work done during the past five years on blood-transfusion. Applications and communications drawing attention to suitable candidates should be sent to Mr. F. W. Mills, National Provincial Bank Ltd., Holborn Circus, E.C.1, before Sept. 30.

Association des Médecins de Langue Française

This association is holding the 26th French congress of medicine in Paris from Oct. 16 to 18 under the presidency of Prof. A. Lemierre. The subjects chosen for discussion include genetics, the anti-histamine drugs, and pulmonary cysts. The secretary of the congress is Prof. L. Justin-Besançon, 38, rue Barbet-de-Jouy, Paris VII.

International Congress of Surgery

Those who wish to attend the XIIth congress of the International Society of Surgery, which is to be held in London from Sept. 14 to 20, should inform the secretary, Mr. H. W. S. Wright, 9, Weymouth Street, W.1, not later than July 31. Applications for membership of the society may of course be made at any time.

Society of Apothecaries

At a recent meeting of the court of assistants with Dr. C. Thackray Parsons, the master, in the chair, the following representatives were appointed: Central Midwives Board, Dr. J. P. Hedley; British Postgraduate Medical School governing body, Sir Cecil Wakeley; Central Council for District Nursing, Mr. George Wynn-Williams; XIth International Congress of Pure and Applied Chemistry, Prof. E. C. Dodds, F.R.S., and Dr. Roche Lynch; Commission Internationale Permanente pour la Médecine du Travail: the Master.

The following were clothed with the livery of the society: Edward Leslie Moll, Philip Willcox, Frank Cook, Henry James Drew Smythe, and Archibald Gilpin. The honorary freedom of the society was bestowed upon Sir Stanley Hewett. The following were admitted to the freedom of the society:—by redemption: Evan Arthur Williams, Nicholas Bickford, Gerald Fitzmaurice Keatinge, Guy Blackburn, William Bentley Purchase, Robert Wilfred Scarff, Noel Gordon Harris, Patrick Butler Adamson, Oliver Broadgate Brears, George Wynn-Williams; by servitude: John Stewart Dismorr. Peter William Monckton Copeman was bound apprentice to William Sydney Charles Copeman for four years.

The mastery of midwifery, honoris causâ, was conferred upon Sir Allen Daley, Sir Eardley Holland, and Sir William Fletcher Shaw. The diploma in industrial health was granted to A. Bell, and the diploma of L.M.S.S.A. to the following:

J. A. Archer-Hall, M. G. Allen-Marsh, A. G. Lewis, G. R. Hollings, R. P. K. Sen, R. D. C. Hart, P. Sattin, F. W. P. Clutterbuck, A. R. Ellerker, J. S. Lambe.

Diary of the Week

JULY 13 TO 19

Monday, 14th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
3.45 P.M. Prof. T. Nicol: Applied Anatomy of the Alimentary Canal.
5 P.M. Dr. N. F. Maclagan Liver Efficiency Tests. (Second lecture.)
MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1
8.30 P.M. Mr. F. A. Williamson-Noble: Contact Lenses. Dr. G. B. Dowling: Athlete's Foot. Mr. A. Dickson Wright: Pruritus Ani.

Tuesday, 15th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Prof. P. C. P. Cloake: Treatment of Disseminated Sclerosis by Artificial Pyrexia and Prolonged Administration of Arsenic. (First Humphry Davy Rolleston lecture.)
ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. J. Kirk: Anatomy of Cerebrospinal Fluid.
5 P.M. Prof. E. C. Dodds, F.R.S.: Hormones.
ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
5.30 P.M. General meeting of fellows.
SOCIETY FOR THE STUDY OF ADDICTION
4 P.M. (Westminster Hospital, Horseferry Road, S.W.1.) Prof. F. L. Golla: Alcohol and the Neuroses. (Kelynack lecture.)

Wednesday, 16th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. M. Kremer: Visceral Sensation.
5 P.M. Dr. E. K. Dawson: Mammary Cancer—its Genesis and Spread. (First lecture.)
TUBERCULOSIS ASSOCIATION & TUBERCULOSIS SOCIETY OF SCOTLAND
2.45 P.M. (Dept. of Zoology, King's Buildings, West Mains Road, Edinburgh.) Dr. H. A. Pattison: Rehabilitation in the U.S.A.
4.45 P.M. Mr. Holmes Sellors: Assessment of the Results of Thoracoplasty.
9.15 P.M. Dr. H. P. Tait: Edinburgh Medical Men at the Time of the Resurrectionists.

Thursday, 17th

ROYAL COLLEGE OF PHYSICIANS
5 P.M. Professor Cloake: Treatment of Disseminated Sclerosis. (Last Humphry Davy Rolleston lecture.)
ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. E. L. Patterson: Ductless Glands. (First lecture.)
5 P.M. Dr. Dawson: Mammary Cancer. (Second lecture.)
6.15 P.M. Prof. J. G. Turner: Movements of Teeth. (Charles Tomes lecture.)
ROYAL SOCIETY OF MEDICINE
5.15 P.M. *Experimental Medicine and Therapeutics* and *Medical Society for the Study of Venereal Disease.* Dr. Earle Moore, Dr. G. L. McElligott, Dr. E. M. Lourie: Treatment of Syphilis with Penicillin.
TUBERCULOSIS ASSOCIATION & TUBERCULOSIS SOCIETY OF SCOTLAND
9.30 A.M. (Edinburgh.) Dr. H. Van den Berg: Control of Results in B.C.G. Trials.
11 A.M. Dr. J. G. Scadding: Pneumonias Associated with Epidemic Respiratory Infections.
2 P.M. Dr. V. Reilly: Pathology of Amyloidosis.
3 P.M. Dr. W. M. Borthwick: Genito-urinary Tuberculosis.
4.45 P.M. Prof. V. Monaldi: Endocavitary Aspiration in the Treatment of Pulmonary Tuberculosis.
BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, W.1
8 P.M. Mr. J. Lawrence: Application of Artificial Radio-activity to Biology and Medicine. (Mackenzie Davidson lecture.)
ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W.1
3 P.M. Dr. I. W. Magill: Modern Anæsthesia. (Bengué lecture.)

Friday, 18th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. Patterson: Ductless Glands. (Second lecture.)
5 P.M. Prof. S. L. Baker: Fracture Callus.

Saturday, 19th

TUBERCULOSIS ASSOCIATION & TUBERCULOSIS SOCIETY OF SCOTLAND
9.30 A.M. Mr. Norman Dott: Skeletal Traction, Surgical Decompression in the Management of Pott's Paraplegia.
11 A.M. Dr. A. MacLean, Dr. B. R. Clarke: Causes for the Breakdown of Discharged Quiescent Cases.

BLOOD ENZYMES AND ACTIVITY OF PENICILLIN ESTERS.—The work by Stedman, Stedman, and White to which Dr. A. Compton referred in his letter on June 28 was published in the *Biochemical Journal*, 1933, 27, 1055.

"NISIN."—With regard to the inhibitory substance, known as nisin, discussed by Mr. Mattick, PH.D., and Mr. Hirsch in THE LANCET of July 5, Messrs. Burroughs Wellcome & Co. (The Wellcome Foundation Ltd.) inform us that 'Nizin' is their registered trade name for a preparation of zinc sulphanilate which is used as an astringent and antiseptic for local application.

should be sufficiently light to enable them to study their cases thoroughly . . . they should be encouraged by group discussions to share their problems and experiences, they must have ready access to libraries . . . above all they must be guided and supervised throughout their period of training."

These desiderata of specialist training cannot be forthcoming at any and every mental hospital—least of all those with a small admission-rate or a propensity to entrust the junior members of the staff with the care the least responsive patients.

THE SPECIALISING CLINICS

Hospitals are more easily seen as elements in the postgraduate educational system than are the diverse voluntary clinics and institutes. Many of these have stimulated some kind of psychiatric activity neglected before their advent, while others have afforded certain educational services at a high self-imposed level; and however we view some of their claims and their divagations from the middle road, everyone must recognise that psychiatry owes them benefits. They are as anomalous educationally as they are in relation to organised health services. But calling something an anomaly is different from calling for its removal or repudiation. On the contrary, the valuable features of these clinics and centres n which a still disputed theory and practice are taught make it desirable that appropriate links should exist for mutual advantage I hope) between certain of them and the postgraduate teaching institute of the university.

THE FOUNDATIONS OF TEACHING

Besides clinical teaching (which will include neurology n particular) there must be some laboratory experience in psychology, in biochemistry and electrophysiology, and n neuropathology. The first of these is a large topic in itself, intrinsically complex and made more difficult by uncertainty as to how much psychology the medical student will learn, what departments of psychology there will be in our universities, and what provision for psychological research and teaching in our psychiatric hospitals. Psychiatry cannot thrive if it is not soundly based on psychology, which is as important to it as physiology; yet no-one would think psychiatrists believed this if he overheard some of them deriding experimental psychology or saw them abasing themselves before a psychological test result as though the Sibyl had spoken.

Finally, psychiatric education must include organised experience of healthy people of all ages and in many environments. How to get this and to keep a sensible proportion between the attention given to it and that given to the more traditional clinical material will be a crux. Joint field-research with psychologists and anthropologists may provide one medium of training. The question is connected with the need for psychiatrists to play a part in the health service for university students, where it exists. This means of demonstrating mental hygiene in action lies so obviously at the door of the university psychiatric clinic and has such patent educational value, if sensibly applied, that it should be striven for, in spite of the obstacles and the many reasons for sober restraint in developing it. It is demoralising for a psychiatric institute to preach mental hygiene, or any other principles of professional conduct, if it does not practise them when it might.

DUTIES OF THE UNIVERSITY

What is the relation of the university psychiatric institute and hospital to all this? Is it to be a school through which pass all the psychiatrists in training in the region clustered around it, or is it to concentrate on the training of a much smaller number to fit them for posts as teachers and research-workers. There can be little doubt about the answer. The Goodenough Committee pointed out that the primary problem in psychiatric education is to build up an adequate supply of teachers. The training of such people, if it is to be as thorough as the furtherance of psychiatry and its relief from its present straits would demand, will absorb the major energies of any university postgraduate schools of psychiatry that may be set up. If schools of this kind are in due course created outside London and Edinburgh, parallel to the undergraduate psychiatric departments, they would still be insufficient to provide the larger part of the training of all recruits to psychiatry.

I say this with a full awareness naturally of the part which the Maudsley courses have played in the training of psychiatrists about to take the diploma in psychological medicine. If the training of psychiatrists could consist chiefly of lectures, demonstrations, and the kind of superficial tuition in case-taking and treatment which can be given to numerous "clinical assistants," then the postgraduate schools could provide the bulk of the training for most or all psychiatrists-to-be. But the training of psychiatrists—even the least ambitious of them—clearly cannot continue to rest on so flimsy and outworn a basis, which, clinically, did little more than supply the deficiencies of undergraduate education in psychiatry, and on the theoretical side practised the vices of spoon-feeding and fact-cramming, which are inescapable in such compressed mass teaching.

There is no need to doubt that the last state of those who were thus prepared for the ordeal by examination was nevertheless often better than the first, and that much positive good has been done by "D.P.M. courses"; but they do not answer the needs of psychiatry at its present stage of development. Although lectures and demonstrations will, of course, be a valuable part of psychiatric teaching in the future, they are educationally of less account than supervised work in clinic and laboratory, seminars or discussions, guided reading, and tutorial sessions—all of which take up so much more teachers' time. Indeed there is a direct conflict of purposes: courses of the D.P.M. type become the bane of genuine psychiatric education if they occupy pupils and teachers alike to the exclusion of studies and work more appropriate to the complex task of psychiatric training.

Postgraduate institutes have therefore the choice of spending most of their energy on contributing all they can to this quasi-universal training, or husbanding their resources for the training of the honours men.

A third choice might lead them to concentrate on some division of psychiatry—for example, the forensic or mental deficiency—and to aim at teaching this on an intensive, or extensive, scale. But the more intensive, the more restricted to a select group; the more extensive, the more it will be of the universal spread-the-butter-thin type; so that what seemed a third choice is really a variant of the two main choices.

Between these two no true compromise seems to me possible: and I am convinced that it is intensive training that the university department should choose as its direct business.

This choice does not shut out the university school from the wider field of psychiatric education: its aim is to increase the influence of the university upon all such education, but that influence can be exercised indirectly and through systematic exposition of aspects of psychiatry and of its basic sciences which can be well taught to classes, rather than by the lowering of standard which necessarily accompanies the clinical teaching of large heterogeneous groups. It is wasteful to put the honours and the pass men in the same class.

I am assuming that, in future, teaching and mental-health services will be so related that the part-time teachers will be much more numerous than in the past, will be drawn from all branches of the mental-health service, will be available for postgraduate as well as undergraduate pupils, and will share in the work of the university clinic. It will be the primary concern of course of insulin, to diagnose a high-grade defective, or to avail himself of the results of psychological tests, he should not have to choose whether he will excuse or hide his deficiencies; he ought not to be nonplussed and as much off his own ground as if he had been called to deliver a baby. His all-round training is not designed to make him a sciolist who thinks he can answer every question, but to put him in the way of getting the experience that will give him scientific grounding, standards, and a sure frame of reference, and will fit him for the general practice of psychological medicine as our times require it.

The psychiatrist, like other specialists, must acquire knowledge, a technical skill, and an attitude fit for what he has to do: he cannot, for example, dislike human beings with a Swiftian rancour, he cannot view his patients' conduct censoriously or be indifferent to their motives and feelings, any more than he can afford to be clumsy in carrying out therapeutic measures or in getting patients to talk to him freely. He may, it is true, become an administrator, or a psycho-analyst, or a forensic expert, or even a professor—very diverse activities, but all requiring the broad training.

I do not believe that it is wise at the beginning of the psychiatrist's training to decide in what field his strength and interests will lie, and thenceforward to put most weight on that: time enough when he has boxed the psychiatric compass. Perhaps in a few exceptional cases now, and generally in that happy day when psychiatry will be taught to medical students with all the thoroughness and amplitude we could wish, it will be possible to curtail or amend the graduate's broad training, using elective courses and individual plans of study: but the time is not ripe for such economy.

You may be disposed to quarrel with my frequent use of the word "training," as though a psychiatrist were an athlete or a circus elephant: and to remind me that I had chosen to speak of education. By the time a man enters on the postgraduate study of psychiatry, his general education should be able to look after itself and should gain from all his experience: if it cannot, the horse is out, and it will be idle to close the stable door by formal teaching. John Locke said, on a similar occasion, "I have seldom or never observed anyone to get the skill of reasoning well, or speaking handsomely, by studying those rules which pretend to teach it." The whole of the psychiatrist's postgraduate studies should train him in reasoning and understanding—what Thomas Lewis called the vital flame in education. And surely example and steady guidance, rather than precepts and "a course," are the best corrective for defects in that general education which should fit a man to combine the scientific and the humane temper in his studies, as the psychiatrist needs to.

Coming from this high ground to the uneven plain where doctors are taught to be competent specialists, I see only two methods as essential there—well-supervised practice (in hospital, laboratory, school, or clinic), and contact with more informed minds wherever these may be found—in books, seminars, educational films, lectures, and case-discussions, and on less formal and didactic occasions.

If the mind of the lecturer, of the author of the textbook, or the conductor of the seminar is dull and petrified, the student carries away no spoils, but only examination-fodder: or if the teacher's mind, versatile and specious, throws out false speculations like sparks, luckless is the student who comes under its spell. Equally unrewarding is clinical work that is not supervised: hence comes the waste of zeal and the naïveté to which attention has been drawn by our critics. Walter Bagehot said that the self-taught and original man is dogmatic, decisive, and detestable. I think it might be said that the clinically self-taught and unoriginal psychiatrist is in danger of being feeble and frothy, and diligently futile.

Clinical teaching must be the core of the psychiatrist's education: "taking cases," studying and treating individual patients, arranging and digesting the findings, formulating the problem, relating it to what may be learnt elsewhere than in the company of the patient—this is the body of psychiatric opportunity.

A recent writer, Karl Menninger, lists the devices that serve the ends of psychiatric education: assigned and recommended readings; the study and care of selected cases; systematic group conferences; individual weekly conferences or control sessions for at least nine months on individual cases under treatment; seminars and didactic [illegible] subjective experiences—e.g., by being psycho-analysed, doing psychological tests, formulating one's autobiography. list could be extended: educational films, demonstrations, the preparation of essays, carrying out a small original investigation, training in laboratory methods, "field studies" of normal children and adults, participation in the work of courts, remand homes, prisons, homes for the aged, personnel departments in industry, social agencies; domiciliary visiting; and so forth. But the essential "device" is clinical practice carried out under suitable direction.

There is much proper emphasis nowadays upon preventive psychiatry, extramural psychiatry, social psychiatry, psychiatry apart from the patient who wants to be treated for an illness: it is clearly necessary that these aspects shall be studied and pursued vigorously. But if they are not to become chimeras fed on catchwords and flighty pretensions, buzzing in a vacuum, then psychiatrists who follow them need clinical training with patients of every sort, just as much as do those of us who pursue more familiar therapeutic aims.

THE USE OF HOSPITALS IN TEACHING

The mental hospitals, which were long the sole, and always the main, training-ground for psychiatrists in this country, have produced so many learned and able men, famous for their contributions to medicine, that it seems impertinent to question their teaching methods. But when the diploma in psychological medicine was introduced, many voices declared the glaring faults of so-called training which consisted in letting psychiatrists learn by doing, undisturbed by any regular instruction. Outstanding improvements have softened the charges then made, but it is still true that in many, if not most, mental hospitals the junior doctors serve an apprenticeship which flouts some of the principles of professional education. I think most of those who have examined candidates for the diploma in psychological medicine would wish the methods of training in mental hospitals improved.

The solution of this problem surely lies not in trying to turn every mental hospital into a postgraduate teaching hospital, but in selecting certain mental hospitals in each region, designating them as having teaching responsibilities for the men and women who begin their psychiatric career in that region, and ensuring that they have the staff and organisation requisite for this. I assume that the new regional organisation will permit the regional authorities to insist that entrants into the mental-health service of the region shall serve during their training years in the designated hospitals. The entrants are not likely to quarrel with this; objections are more likely to come from mental hospitals which do not enjoy the staffing and other advantages of the training hospitals: but these non-teaching mental hospitals will benefit in the quality and experience of the men who come to them after $2^1/_2$ or more years novitiate in the training hospitals.

The designated hospitals would, of course, have outpatient and children's clinics connected with them, and the trainees would have opportunities for learning about mental deficiency and domiciliary psychiatry. The hospitals would, in brief, command all the clinical material needed for training: but this by itself would be of little avail. Sir Francis Fraser has lately repeated the familiar truth that—

> "more is required than clinical material and the usual hospital equipment. The duties assigned to the candidates

profit by taking part in them. One of the chief blems of the postgraduate institute is not to reconcile earch with teaching, but to preserve for both the ditions favourable to them against clinical and adminiative encroachments—what Sir Thomas Lewis has led "the crippling routine which the care of numbers patients renders inevitable," "attendance at comtees, and numerous additional chores." The responsities of each university medical school in assisting development of the National Health Service in its ion will for the next few years throw a further burden the psychiatric in common with other departments—ecessary burden, but one not easily to be carried if full obligation to teach and study disease is being uldered as it ought. A professor, like the bishop of om Hugh Latimer preached, cannot be two men: "hath his office, a flock to teach, to look unto; and erefore he cannot meddle with another office, which ne requireth a whole man: he should therefore give over to whom it is meet, and labour in his own siness."

For kindred reasons, it might be desirable that it should l to the associated non-university training hospitals d clinics, rather than to the postgraduate institute, conduct courses for refreshing the knowledge of alified psychiatrists or of general practitioners, and for ucating special sections of the public. There will, lare say, be far more teaching to be done than teachers do it: we psychiatrists shall need to agree on our ching provinces, therefore, in a condominium, and will l no temptation to scramble for sovereign rights and e power of veto.

Child psychiatry and psycho-analysis—igneous topics ese. As for child psychiatry, I see no valid division the training of psychiatrists which could depend on e age of the patient, and I have no doubt that presently e psychiatry of the old will likewise become a prominent rt of our branch of medicine. The chief problem in spect of children is how to ensure that the psychiaist shall have a good knowledge of general pædiatrics quivalent to his knowledge of general medicine) without lding to the length of his training: and the second oblem is to place the main period of experience with ildren at the most suitable stage of the psychiatrist's ree years of all-round training, before he devotes mself more exclusively to that or any other division of ychiatric study and practice.

Psycho-analysis is an older and thornier educational oblem. It would be absurd to state the arguments offer a tentative solution here. It can be assumed at for a good while to come, at any rate, psychiatrists ll be free to choose whether they will be psycho-analysed not, and that those who teach psycho-analysis will be ee to choose whom they will analyse, and when. But is unseemly that a postgraduate institute, if it holds at psycho-analysis may be valuable in the training of me psychiatrists, should shut itself off from that ork, or profit by it without taking responsibility for , as we have profited—and how much we have profited -by the bold and enlightened educational effort of merican and European centres of psychiatric training, t which so many of us, in the last thirty years, have een nourished or polished. Means must be found, erefore, whereby those pupils of the postgraduate stitute for whom psycho-analysis is judged a useful nd necessary part of their training should be able to et it under university auspices, just as we aim to provide t home as wide and good a training as the best foreign hools afford. Not of course that we want to forgo e advantages of study abroad (a year of such study hould be almost obligatory upon "honours men") or want the university institute to take over—if it ould—all the functions and convictions of the Institute f Psycho-analysis.

The last, and the most practically urgent, question to consider is the determination of the criteria, and the means, through which approval may be given to non-university hospitals and clinics at which doctors can learn psychiatry. At the present time this is attended to, in a blithe and blanket fashion, by the examining bodies which grant a diploma in psychological medicine. The Goodenough Committee propose that—

> "any hospital outside a medical teaching centre that is used for pre-registration house-appointments should be specially approved for the purpose by a university. . . . A university, after approving any hospital, should notify the General Medical Council and that body from time to time should publish a complete list of approved hospitals"; specialist trainees should obtain practical experience "particularly in the hospitals approved by the various universities for the purpose of pre-registration house-appointments."

This is well enough as far as it goes, though naturally it does not allow fully for the peculiar distribution of psychiatric cases. It does, however, put the onus of approval on the universities, and since it is proposed elsewhere in their report that the award of a diploma in psychological medicine should be solely vested in the Royal Colleges, the committee evidently decided that the bodies which should grant or withhold approval ought to be not the diploma-giving but the education-giving institutions. This is rational, and puts the primary duty of approval in the hands of those qualified to judge the fitness of the hospitals and clinics in their region. It could only be exercised fairly if minimal criteria of approval were laid down, and some open method of inspection and appraisal used.

* * *

It is hard to tell how soon it will be possible to come at the full means for realising aims now generally agreed upon by all of us. To realise these aims I think we must get away from the D.P.M. outlook, as I may call it, in psychiatric education. At its worst this outlook has created psychiatrists who are bare empirics, and teachers of psychiatry who are like the sophists that Aristotle denounced—"they used to suppose that they trained people by imparting to them not the art but its products."

What are its outstanding faults? Too many examining bodies have made a uniform standard almost impossible, and a high standard quite impossible. The psychiatrist has been encouraged to nibble at many branches of knowledge instead of studying them, and has often come to regard the experts in these—for example the psychologist—as rivals or subordinates, as technicians, as academic playboys, as masters of strange and efficacious arts, as anything but scientists and collaborators on whom he intelligently depends. His training has not saved him, in psychopathology, from a weak syncretism. Therapeutic effort has prospered at the expense of therapeutic discrimination.

Perhaps I lay too much of this at the door of the "D.P.M. outlook"; these things may bespeak wider faults than inhere in the D.P.M. course and examination: and we have now in any case the promise of a better system of psychiatric education, and a better D.P.M., likely to advance psychiatry greatly. But, mindful of much public misunderstanding of what psychiatrists can do and what psychiatry stands for, we can heed the assurance of a Victorian, "Depend upon it, there is only one way of really ennobling any calling, and that is to make those who pursue it real masters of their craft, men who can truly do that which they profess to be able to do." If the education of the psychiatrist does that, and produces men capable of adding to the knowledge that will advance psychiatry, then, whatever its shortcomings, it will have deserved well of our generation.

the university postgraduate clinic to find and train the men and women of outstanding promise—future administrators, psychotherapists, consultants, whole-time teachers—psychiatrists of every name and bent—who will have through their knowledge and achievement *something valuable to pass on to others.*

What I am proposing is perhaps open to the objection of privilege: you are pretending to separate sheep from goats (it may be resentfully said) with your "honours men" and "pass men," trying to skim off the cream, favouring smooth Jacob before homely Esau, reserving the honey for the queen bees (who may turn out to be drones). But in fact many psychiatrists seem to take a view of the training needed and attainable by most of those who practise our specialty that is far below anything implied or intended in what I have said. They hold that the clinical requirements laid down by the R.C.P. committee are far too exacting: many, for example, agreed with Sir Laurence Brock when he said in the twentieth Maudsley lecture that it would be disastrous to regard as psychiatrists only those who have taken a five years' course of preparation and training; and there was at one time support for the proposal to have a not very exacting common diploma for the bulk of psychiatrists, and a higher, more specialised, one for the illuminati. I hold, against such views, that psychiatry requires a high level of all-round training in everyone who practises it, and I would strongly oppose a two-level diploma: though I hold, equally strongly, that during professional training, as in every educational system, there is need to take account of those differences in endowment, interests, and probable achievement of students which psychologists and psychiatrists realise better than any.

A three-year or five-year period of training would not, of course, be spent wholly within the university clinic and laboratories: just as the postgraduates who receive their nuclear clinical training in mental hospitals and attached outpatient departments would come to the university for certain lectures and studies, so the postgraduates of the university hospital would go to certain mental hospitals and other places for parts of their training.

What has the university clinic or institute to offer, that it can claim the chief place in the education of psychiatrists? First, I answer, the qualities that mark it off from the technical school. Vocational training is, of course, essential for the doctor, but by itself can produce a medical craftsman, not a physician, and least of all a psychiatrist. Students should find in the university clinic the ferment and the opportunity which Flexner had in mind, I think, when he said that medicine can be learnt but cannot be *taught.* The *postgraduate* student, bringing his own passion and energy, learns there to respond to the vigorous and often creative impact of other minds. Anyone who has worked in an active university clinic knows how much he owed to the congregation of fellow-students, to their ardent, critical, lively, disputatious, reflective, eager minds.

More material advantages the university clinic also offers—its libraries and laboratories, its easy contact with other university departments, its facilities for research, its right to select and restrict its patients for the purposes of teaching or research: these are indeed solid advantages, but I see no reason why they should not be at the disposal also of those who pursue postgraduate studies in mental hospitals and other non-university institutions and clinics. And it is not in these material advantages that we find the true virtue and promise of the university clinic.

UNDERGRADUATE TEACHING

The relationship of the postgraduate to the undergraduate school will have to be considered. Where, as in London, there is an entirely separate po institute of psychiatry, and more than one un school with psychiatric beds, and appointments for physicians and registrars, the problem is very from that which confronts the professorial ps unit with undergraduate teaching as its chief duty, no postgraduate institute alongside it: is such a to take the main responsibility for the postgr teaching of psychiatry in its region? The G Committee appeared to think this course d *they would encourage the assumption of* such bilities by the teaching school and its associated "to the fullest possible extent consistent with primary educational responsibility for the training undergraduate students." While the benefits of are patent, it seems a much less suitable pla psychiatry than for most other specialties, because of the shortage of teaching staff in the existing or undergraduate departments of psychiatry, and the tively large number of entrants who will be required each year by the mental-health services: their instruction would be a drain on the teaching energy and of the medical-school staff, which would conflict much with their primary obligation to the undergr even if desirable as an objective, it would be hard to into practice generally during the critical decade us. In that time it would surely be better to mainly upon the parallel non-university complex selected mental hospitals and clinics to which I referred as the inevitable and proper adjunct of postgraduate institute of psychiatry, where that Where the postgraduate institute does not exist, advisory and adjuvant functions towards the non-university specialist hospitals could be carried by the undergraduate department. There will of course, be a small number of men receiving graduate *training in that department* through and staff appointments.

SOME RECIPROCITIES

Then there is the relationship of the psychiatric institute to the university department of psychology. A psychological laboratory seems an essential part of any active psychiatric institute—a psychological laboratory, that is, not merely to meet the clinical needs of diagnosis and treatment, but with teaching research in the front of its activity, staffed accordingly, and in the closest touch with the main university d ment of psychology. I can see no ground for here, but only for mutual aid. No doubt the medi school would take a hand in the postgraduate of psychologists, especially for purposes close to medicine while the department of psychology might undertake some of the necessary psychological education of psychiatrist, wherever the necessary admin adjustments could be made.

The kinship between psychiatry and the social sciences raises similar issues, to be similarly handled by fraternal interchange and reciprocal increase. The truth is for its various purposes the psychiatric institute be able to take its problems, and its requests for aid teaching, to any of its sister departments: stati genetics, pharmacology, industrial medicine, anthropology, pædiatrics, psychology, and many more, as the occasion demands.

As to the relationship of the teaching psychiatric hospital to the treatment of the sick, it is now well stood that it is the duty of the teaching unit to select cases for its particular needs, rather than to accept and sundry; equally it is its duty to treat the pati it accepts, in the most thorough, skilled, and effec way. The interdependence of teaching and resea is generally recognised. Research projects mor provide indispensable education for those at a ive-sixths of what appears to be his normal stomach, with the likelihood that the ulcerated part of the duodenum will be left. Cannot surgery offer some less adical operation than gastrectomy, with all its attendant isks and disabilities—some operation which can give at east as good a chance of permanent cure? It is contended that vagal resection is a safe and effective lternative to gastrectomy, and we have tried it in 0 cases with results which are so far promising.

VAGAL RESECTION

Rationale.—Patients with duodenal ulcer are typically subjects with hypermotile hypersecreting stomachs. Evidence has been adduced by Berk et al. (1942a and b) that they also fail adequately to neutralise acid in the duodenal bulb.

Since the introduction by Code and Varco (1940) of the histamine-beeswax method of inducing continuous hypersecretion in laboratory animals, it has become apparent that this alone is sufficient to cause chronic peptic ulcers similar to those found in man.

Further, Mann and Williamson (1923) have shown that side-tracking the alkaline secretion of the pancreas and the bile, even in the absence of artificial hyperacidity, will be followed by similar lesions at the site of ejection of the gastric chyme against the mucosa of the small ntestine.

Stahnke (1924, 1925) produced ulcers by repeated stimulation of the vagi, and vagal irritation was probably the cause of those studied by Cushing (1932) which were associated with hypothalamic injury and disease.

Recent investigations by one of us (H. D. J.) on nocturnal gastric secretion have shown that during sleep the acidity reaches very high levels, sometimes twice as high as those attained with histamine injection. Dragstedt (1947) states that the volume of secretion in duodenal-ulcer patients is excessive, and Bollman and Mann (1932) have shown that even in normal people neutralising power tends to tire if acid secretion is over-prolonged.

Since at night there is no food in the stomach to stimulate secretion by hormonal action, Dragstedt assumed that this secretion was neurogenic, and he found that vagal section in dogs reduced the volume of resting secretion to less than half and would considerably lower its acidity (Dragstedt and Ellis 1930).

The paramount factors in the establishment of chronicity in duodenal ulceration appear to be hypermotility plus a failure of adequate neutralisation of acid in the duodenum, and the object of vagotomy is to reduce both the motility of the stomach and the quantity of free hydrochloric acid leaving it, so making neutralisation easier.

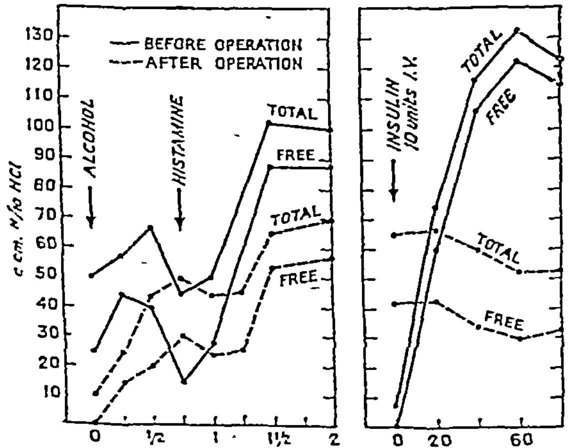

Fig. 2—Free HCl and total acid with alcohol, histamine, and insulin test-meals, before and fourteen days after vagal resection, in a man aged 46 with nine years' duodenal ulcer.

Division of the vagi at the lower end of the œsophagus eliminates the psychic phase of gastric secretion, and, as Hollander (1944, 1946) showed, abolishes the acid response to hypoglycæmia.

Vagotomy does not affect the response to ingested food, which is under hormonal control, but the mealtime secretion is well buffered by the food and is relatively harmless. The fasting night secretion is the real danger, and, as Dragstedt (1945) showed, vagotomy considerably reduces its volume and to a variable degree its free acidity.

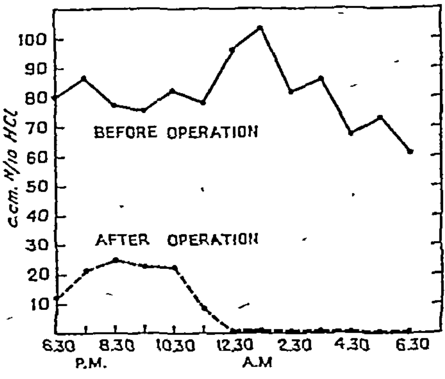

Fig. 3—Free HCl in hourly samples of spontaneous gastric secretion during sleep, before and fourteen days after vagal resection combined with gastro-enterostomy, in a man aged 20 with seven years' duodenal ulcer with pyloric stenosis after perforation.

Coffee and tea have a well-marked stimulating effect on gastric secretion, and peptic ulcers of the chronic type have been produced by the injection of caffeine in animals (Merendino et al. 1945). More recently Roth and Ivy (1945) have demonstrated that at least part of the effect of caffeine is central, mediated through the vagus.

It is reasonable to suppose, though difficult to prove, that the vagus is the pathway along which emotional factors influence the stomach, and it is well known how closely emotional upsets are related to the onset of ulcer symptoms. Wolf and Wolff (1944) have observed, through a gastrostomy opening, that feelings of resentment are accompanied by hyperæmia and turgidity of the gastric mucosa and increased secretion. More recently Wolf (cited by Andrus 1947) has observed that after vagotomy the stomach loses this capacity to flush with anger.

Section of the vagi also reduces gastric and duodenal motility and abolishes the excessively rapid emptying often found in cases of duodenal ulcer, thereby giving more time for neutralisation, buffering, and physical adsorption of hydrochloric acid before it leaves the stomach.

As Patterson and Sandweiss (1942) have shown, duodenal ulcer distress is felt only when the duodenum is actively contracting, and it is probably by the prevention of spasm that vagotomy gives immediate symptomatic relief. Abolition of spasm is also likely to be an important factor in the rapid healing of the ulcer which is practically always observed.

There is some evidence that ulcer distress is itself a stimulus to further secretion; hence a vicious circle is established of hypersecretion-ulceration-pain-hypersecretion. Vagotomy breaks this circle in two places, by relieving painful spasm and by cutting the neural pathway for reflex hypersecretion.

Dragstedt (1945), Moore et al. (1946, 1947), and Ruffin et al. (1946) have analysed series of 39, 37, and 30 patients submitted to vagotomy, all specially selected for intractability. The follow-ups are relatively short, but the results may fairly be described as promising.

Side Effects.—Vagotomy has been done a great many times in the course of other operations, such as gastrec-

VAGAL RESECTION IN THE TREATMENT OF DUODENAL ULCER

From the Department of Surgery, British Postgraduate Medical School

The incidence of chronic and recurrent ulceration of the duodenum is increasing fast and unchecked and is already a problem of national concern.

Tidy (1941, 1943) has emphasised this by comparing the numbers of discharges from the Army for peptic ulceration in the two world wars. The figures for comparable periods showed a 300-fold increase for the late war. Tidy also states that the death-rate from this disease has increased several times over since 1918, in spite of a considerable improvement in the treatment of its dangerous complications.

Bashford and Scott (1935) reported that, among Post Office workers proved to have duodenal ulcer, over 30% were subsequently absent from work because of this complaint for more than a month per year, the average for all cases being fifteen days per year.

Avery Jones (personal communication) estimates that over 5% of men in industry and transport now have duodenal ulcer. This is equivalent to a labour force of many thousands permanently idle, or a loss of earning power of several million pounds a year. This morbidity and loss of working hours is formidable enough, but the damage to morale and human happiness can only be guessed.

Allen and Welch (1942) have estimated that among hospital outpatients 20% of the duodenal ulcers are intractable or relapse under medical care, and that of these a quarter perforate, a quarter have operations for obstruction, and half come to surgery for hæmorrhage or intractable pain.

WHAT HAS MEDICINE TO OFFER ?

While it is admitted that 20% of duodenal ulcers are surgical problems from the start, it is usually claimed that the other 80% can be healed by proper medical management. But at present hospital beds can be spared for only very few of these patients, and treatment at home is not often adequate. The healing of one ulcer is seldom the last incident in the disease. Thus St. John and Flood (1939), after carefully following 225 patients treated medically, found that 65% relapsed within two years.

The real problem in this condition is not so much one of healing a single ulcer as of preventing recurrence. The work of Greengard et al. (1946) suggests that enterogastrone may one day become an important prophylactic agent, and King et al. (1944) have had promising results in experiments with secretin ; but so far it cannot be claimed that a régime has been evolved which can control the tendency to relapse. Nor can one ignore the risks which go with recurring ulcers. Even in the young age-group of serving soldiers, Berk and Frediani (1944) found that already 7·6% had perforated and 17·7% had bled.

WHAT CAN SURGERY OFFER ?

Gastro-enterostomy.—Though many consider that gastro-enterostomy is still the operation of choice for a duodenal ulcer with long-standing pyloric stenosis, where the power to secrete acid is diminished, it is now beyond doubt that it is worse than useless in a high proportion of the typical ulcer patients with hypermotile and hypersecreting stomachs.

St. John et al. (1939) analysed a follow-up of 225 patients who had been submitted to gastro-enterostomy with an operative mortality of 10%. Of 121 patients traced in whom the indication for operation had not been pyloric stenosis, 69 were classified as unsatisfactory. Of these, 31 had new ulcers, 24 had bled, 14 had had further surgery, and 3 had died of ulcer.

According to the collective inquiry of the Association of Surgeons (1935) into over 2000 gastro-enterostomies, only 8·4% had proved or suspected recurrent ulcers ; but only three-quarters of the patients were traced, and the report does not tell us what criteria for diagnosis were adopted or how many patients had symptoms not regarded as due to ulcer. Further, a relatively low figure may be obtained by including many cases which would have been equally amenable to medical treatment.

Lewisohn (1945) reports 80% "failures" and 34% of gastrojejunal ulcers after gastro-enterostomy.

Gastrectomy.—*After such results surgeons,* led by Von Haberer, turned to gastrectomy as an alternative. The first resections were not sufficiently radical, and stomal ulcers continued to be common. It is now established that *all* antral mucosa must be ablated, as well as enough of the body of the stomach to cause achlorhydria, if anastomotic ulcers are to be prevented. The average gastrectomy for duodenal ulcer still seldom achieves achlorhydria ; and, as was brought out by the Association of Surgeons (1935), the postoperative level of acidity can be correlated with the incidence of subsequent gastrojejunal ulceration.

Reinhoff (1945) described 260 hemigastrectomies with only 5 deaths but with 32% of subsequent complications, including 11% of patients requiring further surgery, 9% of proved recurrent ulcers, and others with hæmorrhage and pain.

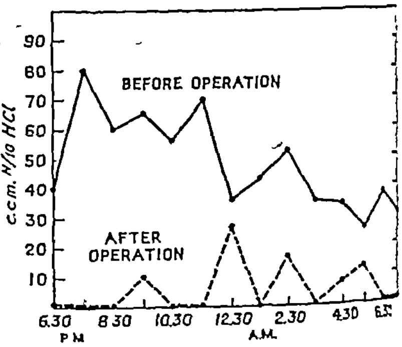

Fig. 1—Free HCl in hourly samples of spontaneous gastric secretion during sleep, before and fourteen days after vagal resection, in a man aged 35 with twenty years' *dyspepsia and proved duodenal ulcer*

Mage (1942) recorded 502 less conservative resections for duodenal ulcer which were followed in 8% of cases by gastrojejunal recurrence.

A well-analysed report is that of Allen and Welch (1946), who performed 190 elective gastrectomies for this lesion with an operative loss of 5 (2·6%). In 129 cases followed from one to fourteen years they found 3 proved ulcers, 3 patients with hæmorrhage, and 3 others with severe symptoms. There were a further 8 considered satisfactory but with moderate symptoms, and 23 excellent but not symptom-free. Altogether there were 10% of total failures and only 67% rendered asymptomatic.

Even though it excludes cases of acute hæmorrhage, the figure of 2·6% for operative deaths is low. The operative *mortality among over 2500* gastrectomies performed by Finsterer, Von Haberer, Burke, Schoemaker, Bruusgaard, and Balfour works out at 5%, and some of the most skilled operators, both in this country and abroad, have since reduced *their* mortalities to 1% or 2% ; but such results are exceptional, and it is unlikely that the average figure, though constantly improving, is yet less than 5%. Thus, though the results are better than *those* which followed gastro-enterostomy, gastrectomy is a more dangerous operation, for the former probably now carries less than a 2% risk in average hands.

Operative mortalities, further, do not give a complete picture of the formidable nature of gastrectomy, for in the series of Allen and Welch there were an additional 12% of patients who had more or less severe immediate postoperative complications, and the later "post-gastrectomy syndrome" is now a recognised clinical entity (Adlersberg and Hammerschlag 1947).

No wonder there is some hesitation in advising a patient with duodenal ulcer to submit to the removal of ve-sixths of what appears to be his normal stomach, ith the likelihood that the ulcerated part of the uodenum will be left. Cannot surgery offer some less dical operation than gastrectomy, with all its attendant sks and disabilities—some operation which can give at ast as good a chance of permanent cure? It is ontended that vagal resection is a safe and effective lternative to gastrectomy, and we have tried it in 0 cases with results which are so far promising.

VAGAL RESECTION

Rationale.—Patients with duodenal ulcer are typically ubjects with hypermotile hypersecreting stomachs. Evidence has been adduced by Berk et al. (1942a and b) hat they also fail adequately to neutralise acid in the duodenal bulb.

Since the introduction by Code and Varco (1940) of the histamine-beeswax method of inducing continuous hypersecretion in laboratory animals, it has become apparent that this alone is sufficient to cause chronic peptic ulcers similar to those found in man.

Further, Mann and Williamson (1923) have shown that side-tracking the alkaline secretion of the pancreas and the bile, even in the absence of artificial hyperacidity, will be followed by similar lesions at the site of ejection of the gastric chyme against the mucosa of the small ntestine.

Stahnke (1924, 1925) produced ulcers by repeated stimulation of the vagi, and vagal irritation was probably the cause of those studied by Cushing (1932) which were associated with hypothalamic injury and disease.

Recent investigations by one of us (H. D. J.) on nocturnal gastric secretion have shown that during sleep the acidity reaches very high levels, sometimes twice as high as those attained with histamine injection. Dragstedt (1947) states that the volume of secretion in duodenal-ulcer patients is excessive, and Bollman and Mann (1932) have shown that even in normal people neutralising power tends to tire if acid secretion is over-prolonged.

Since at night there is no food in the stomach to stimulate secretion by hormonal action, Dragstedt assumed that this secretion was neurogenic, and he found that vagal section in dogs reduced the volume of resting secretion to less than half and would considerably lower its acidity (Dragstedt and Ellis 1930).

The paramount factors in the establishment of chronicity in duodenal ulceration appear to be hypermotility plus a failure of adequate neutralisation of acid in the duodenum, and the object of vagotomy is to reduce both the motility of the stomach and the quantit of free hydrochloric acid leaving it, so making neutralisation easier.

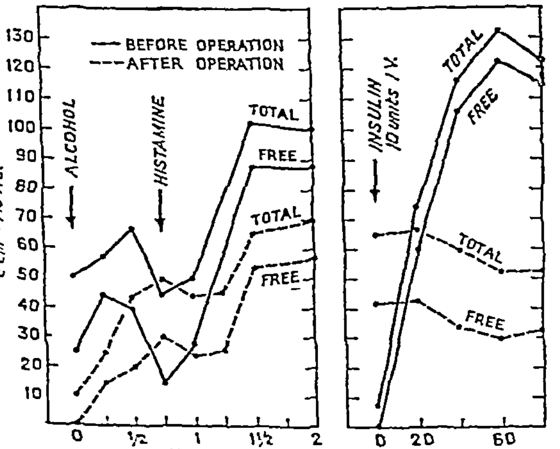

Fig. 2—Free HCl and total acid with alcohol, histamine, and insulin test-meals, before and fourteen days after vagal resection, in a man aged 46 with nine years' duodenal ulcer.

Division of the vagi at the lower end of the œsophagu eliminates the psychic phase of gastric secretion, and as Hollander (1944, 1946) showed, abolishes the aci response to hypoglycæmia.

Vagotomy does not affect the response to ingeste food, which is under hormonal control, but the mealtime secretion is well buffered by the food and is relatively harmless. The fasting night secretion is the real danger, and, as Dragstedt (1945) showed, vagotomy considerably reduces its volume and to a variable degree its free acidity.

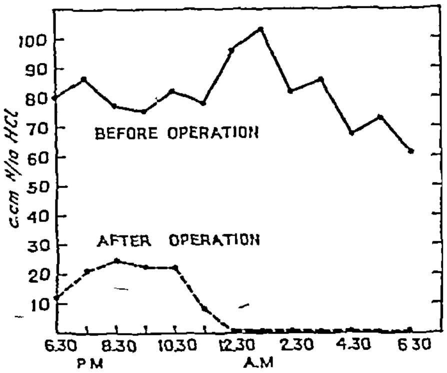

Fig. 3—Free HCl in hourly samples of spontaneous gastric secretion during sleep, before and fourteen days after vagal resection combined with gastro-enterostomy, in a man aged 20 with seven years' duodenal ulcer with pyloric stenosis after perforation.

Coffee and tea have a well-marked stimulating effect on gastric secretion, and peptic ulcers of the chronic type have been produced by the injection of caffeine in animals (Merendino et al. 1945). More recently Roth and Ivy (1945) have demonstrated that at least part of the effect of caffeine is central, mediated through the vagus.

It is reasonable to suppose, though difficult to prove, that the vagus is the pathway along which emotional factors influence the stomach, and it is well known how closely emotional upsets are related to the onset of ulcer symptoms. Wolf and Wolff (1944) have observed, through a gastrostomy opening, that feelings of resentment are accompanied by hyperæmia and turgidity of the gastric mucosa and increased secretion. More recently Wolf (cited by Andrus 1947) has observed that after vagotomy the stomach loses this capacity to flush with anger.

Section of the vagi also reduces gastric and duodenal motility and abolishes the excessively rapid emptying often found in cases of duodenal ulcer, thereby giving more time for neutralisation, buffering, and physical adsorption of hydrochloric acid before it leaves the stomach.

As Patterson and Sandweiss (1942) have shown, duodenal ulcer distress is felt only when the duodenum is actively contracting, and it is probably by the prevention of spasm that vagotomy gives immediate symptomatic relief. Abolition of spasm is also likely to be an important factor in the rapid healing of the ulcer which is practically always observed.

There is some evidence that ulcer distress is itself a stimulus to further secretion; hence a vicious circle is established of hypersecretion-ulceration-pain-hypersecretion. Vagotomy breaks this circle in two places, by relieving painful spasm and by cutting the neural pathway for reflex hypersecretion.

Dragstedt (1945), Moore et al. (1946, 1947), and Ruffin et al. (1946) have analysed series of 39, 37, and 30 patients submitted to vagotomy, all specially selected for intractability. The follow-ups are relatively short, but the results may fairly be described as promising.

Side Effects.—Vagotomy has been done a great many times in the course of other operations, such as gastrectomy or œsophagectomy, without any specific side effects being observed. Animal experiments show that the secretion of the pancreas is slightly reduced by vagotomy, but not to an extent comparable with the gastric effect (Crider and Thomas 1944). The secretion of bile appears to be unaffected (Boyden and Van Buskirk 1943).

The chronic constipation common in patients with duodenal ulcer is cured by this operation. One daily motion seems to be usual after vagotomy, but 3 patients in the series here published had transient diarrhœa which lasted two weeks.

The delay in gastric emptying after vagotomy is sometimes considerable, but this seldom causes any symptoms. Tone gradually returns, though exceptional cases have been recorded in which full recovery has taken several months. Hypermotility and hypersecretion do not appear to return, and the pathway for neurogenic activity, both secretory and motor, remains permanently ablated.

In the presence of hypermotility early pyloric stenosis may escape recognition, since it may do no more than reduce a rapid emptying time to one within normal limits. Reduced gastric tone after vagotomy has occasionally caused such an unsuspected stenosis to come to light.

It has recently been reported by Machella et al. (1947) that normal gastric peristalsis can if necessary be restored by the administration of urethane of β-methyl choline, either by injection or by mouth.

INDICATIONS FOR VAGAL RESECTION

(1) *Duodenal Ulcer.*—The ideal subject is the young patient with a long history of relapses, a clear anxiety factor, not too much scarring or penetration, and no psychopathic factor in his symptoms. Vagal resection is likely to be recommended for the difficult case in which it is felt that medical measures are not maintaining a tolerable and reasonable level of usefulness and enjoyment of life but hesitation is felt in undertaking gastrectomy. Winkelstein and Berg (1938) have advocated the combination of gastrectomy with vagotomy, and perhaps, if this is done, a more conservative resection may achieve the desired achlorhydria.

Vagal resection alone, however, is safe, and there seems to be no justification for taking the risks of gastrectomy without first giving simple vagal section a trial. *Gastrectomy is still in reserve if further treatment becomes necessary.*

(2) *Gastric Ulcer.*—In our view gastrectomy should continue to be the operation of choice for gastric ulcer, but the addition of vagal resection may be considered where high acid secretion has been found.

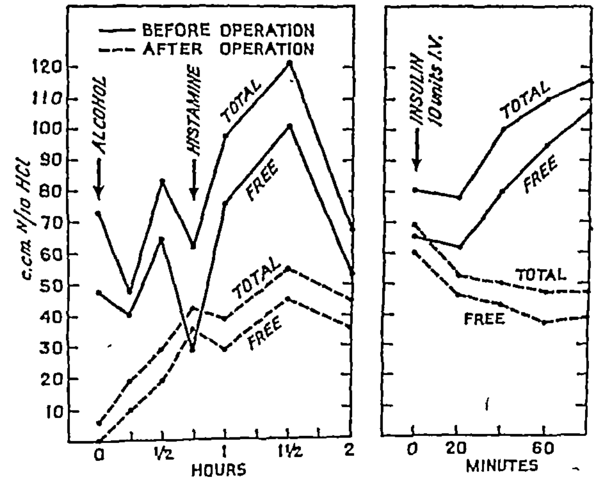

Fig. 4—Free HCl and total acid with alcohol, histamine, and insulin test-meals before and fourteen days after vagal resection combined with gastro-enterostomy, in same patient as in fig. 3.

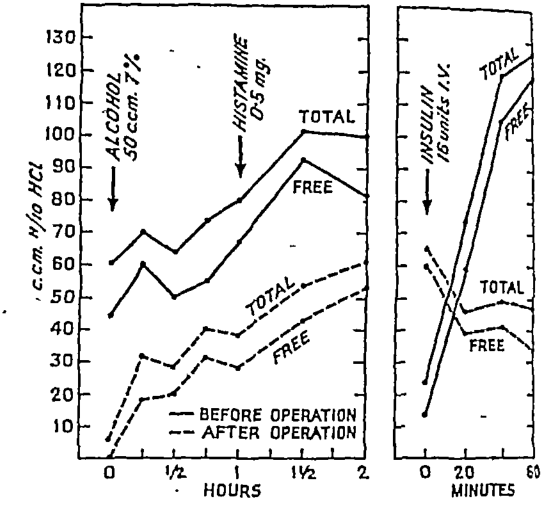

Fig. 5—Free HCl and total acid with alcohol, histamine, and insulin test-meals, before and four months after vagal resection, in a man aged 51 with twelve years' history of duodenal ulcer, showing a recovery of response to insulin.

(3) *Stomal Ulcer.*—Whatever else is done, stomal ulcer is a good indication for vagal resection as an added step. *Good results have been claimed in cases where vagotomy alone has been used.*

ANATOMICAL CONSIDERATIONS

The nerve-supply to the stomach is well described by Mitchell (1938, 1940), whose observations go to show that the vagi descending on either side of the œsophagus divide below the roots of the lungs into 2–4 main trunks lying close to the lower œsophagus. Branches from the left vagus pass to the right and from the right vagus to the left, forming a bewildering plexus. Our observations at operation show that from their main trunks small filaments pass into the muscular wall of the œsophagus above the diaphragm and travel to the stomach, so that section of the vagi below the diaphragm can never lead to complete vagal denervation of the stomach.

Immediately above the diaphragm, or actually within the hiatus, the vagal trunks group themselves into two main components. The left or anterior vagus is found closely applied to the anterior surface of the œsophagus in two divisions which pass down upon the cardia of the stomach. The right division supplies a branch to the hilum of the liver.

The posterior or right vagus is the larger and is found as one large trunk lying in loose connective tissue behind the œsophagus.

It is therefore obvious that the most convenient place to locate the vagi is in the hiatus of the diaphragm, where they form well-marked trunks; but for vagotomy to be complete they must be stripped up and down to sever the minute filaments entering the œsophageal wall, and section must be made above the diaphragm.

OPERATIVE TECHNIQUE

Apart from the methods described by Latarjet (1921), Exner and Schwartzmann (1912), and Steirlin (1920), all of which aim at a partial denervation, there are three main approaches to the vagus. All three have been used by us with various degrees of success.

(1) *Subdiaphragmatic Vagotomy.*—As its name suggests, the first approach is made through the abdomen. The nerves are found close to the cardia and there divided. The method is described by Wertheimer (1922). Its advantages are that it is easy, it is safe, and it may be

ombined with other abdominal procedures if desired. Ve have used it in 15 cases and have found that complete agotomy was achieved in none. All our failures have ccurred in this group.

(2) *Transthoracic Vagal Resection.*—This is the method escribed and advocated by American writers. Dragstedt 1947) reports favourably on 140 cases, some of the tients having been followed for four years. Moore al. (1946) and Grimson et al. (1945) have also been ourably impressed by the results of this method, and many leading clinics in America it has almost entirely pplanted subtotal gastrectomy in the surgical treatnt of refractory duodenal ulcers. The approach is rough the bed of the left eighth rib. The nerves are ught in the cellular tissues below the lung roots and e stripped down to the hiatus in the diaphragm.

It is undoubtedly the method which affords the rgeon the best exposure and provides an opportunity perform the most complete denervation; but its sadvantages are considerable: it is a severe strain on e patient; convalescence is prolonged; and there are sks associated with pleural effusion, which may require spiration, and several cases of empyema have been ported. We have used it on three occasions when e effects of previous operative procedures within the domen would have made a transabdominal approach fficult. The cardinal disadvantage, however, is that e lesion in the duodenum cannot be seen and verified. he possibility of other abdominal lesions cannot e excluded; and, if it is necessary to combine the agal resection with some other operative procedure, ch as gastro-enterostomy, a second operation is quired.

(3) *Per-hiatal Vagal Resection from Below.*—It has een our aim in this investigation to evolve a technique roviding the completeness of the transthoracic resection ith the advantages of a transabdominal approach. he operation will be described in detail elsewhere. Its ssentials are exploration of the abdomen, mobilisation f the left lobe of the liver, enlargement of the hiatus n the diaphragm with mobilisation of the lower end of the esophagus, isolation of the vagal trunks at the level of he diaphragm, stripping of the vagi from the œsophagus pwards into the mediastinum and down to the cardia, nd finally removal of a length of nerve from all trunks. ther procedures can, if desired, be combined with the agal resection, and the possibility of other lesions ithin the abdomen excluded.

The technique is not easy. It demands perfect anæshesia, perfect lighting, and skilled assistance; but, hen it is performed by an experienced team, the strain n the patient is negligible and the postoperative course smooth and uneventful. The patient is allowed out of bed on the second day after operation, and invariably, if he has been suffering pain before operation, he is emphatic that his pain has gone immediately after it.

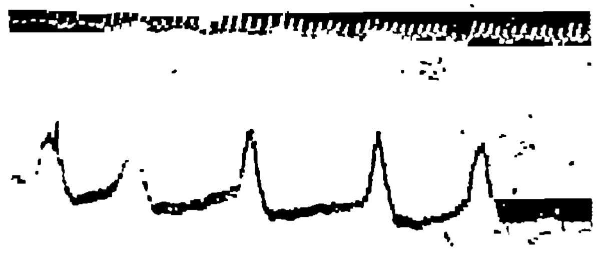

Fig. 6—Kymograph tracing showing changes in intragastric pressure in a man aged 51 with twenty years' history of duodenal ulcer. Lower tracing, before operation, shows (1) respiratory effect (frequent small wave at 20 per min.), (2) tonus waves (just discernible undulations at 3 per min., probably peristaltic), and (3) intermittent spasms of the whole stomach (tallest peaks—occurring at 1-2 min. intervals). Upper tracing was made after vagal resection and shows absence of gastric spasms. Record was continued for two hours. Before operation, gastric spasms were quiescent for periods of only a few minutes during the hour of observation.

INTERIM RESULTS

We have done 50 vagotomies or vagal resections in this series during the past two years without a death. The only serious postoperative complication was an empyema following a transthoracic resection. All the cases have been followed, and the results so far may be summarised as follows:

Incomplete Vagal Resections		*Complete Vagal Resections*	
Average follow-up period	1 yr. 7 mths.	Average follow-up period	6 mths.
Longest follow-up period	2 yr. 7 mths.	Longest follow-up period	1 yr. 4 mths.
Average titratable "free" HCl in whole of night secretion—		Average titratable "free" HCl in whole of night secretion—	
Before operation ..	50 c cm. of N/10 HCl%	Before operation ..	43 c.cm. of N/10 HCl%
After operation ..	31 c.cm. of N/10 HCl%	After operation ..	7 c.cm. of N/10 HCl%

	Cases		*Cases*
Bad	1	Bad, poor, or fair ..	0
Poor	3	Good	4
Fair	1	Excellent	30
Good	7		
Excellent	4		
Total ..	16	Total ..	34

Bad.—No patient has yet complained of worse symptoms after vagal resection; 1 patient died from a massive hæmorrhage three months after a partial operation.

Poor.—No relief, or moderate relief only.

Fair.—Definite reduction in frequency and severity of symptoms, but not symptom-free.

Good.—Ulcer pain absent since operation; on full work, but with varied and slight discomfort, such as "wind" or need to avoid certain foods.

Excellent.—Completely symptom-free since operation, on full work and full diet, and with definite improvement in mental outlook.

The operations on these 50 patients have been spread over the last $2^1/_2$ years. In no case is the report long enough after operation to justify a final evaluation of results.

Subdiaphragmatic Vagotomy.—In 15 patients the subdiaphragmatic route was used, and in these vagotomy was incomplete, as shown by the insulin test. One of the patients died three months after operation from a massive hæmorrhage from his ulcer; 3 continued to have symptoms; 5 have continued at full work enjoying good health for two years; and 3 subsequently developed stenosis requiring gastro-enterostomy but have remained well since that was performed. The remaining 3 have been followed for over two years and have continued at work, with occasional discomfort requiring restriction in diet or medication. In all this group, save the 3 who were not improved, the stomach lost its hypermotility and the ulcer appeared on subsequent radiography to have healed. In few cases, however, was there an appreciable fall in gastric acidity, and in no case was there a negative response to an insulin test-meal. One may infer that this procedure, while likely to benefit the less highly acid type of ulcer, is of little or no value in the treatment of the duodenal ulcer associated with excessive acid secretion.

Transthoracic Vagal Resection.—In 3 patients transthoracic resection was done. Two of these resections were for duodenal ulcer, and one for stomal ulcer following a previous gastro-enterostomy. In all 3 patients (the first now a year after operation) the acidity has fallen to, and remained at, a low level. All 3 patients are symptom-free, but 2 were incapacitated for several months following the operation by discomfort in the chest wall. This operation appears to have a place in cases of stomal ulcer or when adhesions, the result of previous intervention, render difficult an exposure of the hiatus from below.

Per-hiatal Vagal Resection from Below.—This operation, which we prefer, was performed on 32 patients, all tomy or œsophagectomy, without any specific side effects being observed. Animal experiments show that the secretion of the pancreas is slightly reduced by vagotomy, but not to an extent comparable with the gastric effect (Crider and Thomas 1944). The secretion of bile appears to be unaffected (Boyden and Van Buskirk 1943).

The chronic constipation common in patients with duodenal ulcer is cured by this operation. One daily motion seems to be usual after vagotomy, but 3 patients in the series here published had transient diarrhœa which lasted two weeks.

The delay in gastric emptying after vagotomy is sometimes considerable, but this seldom causes any symptoms. Tone gradually returns, though exceptional cases have been recorded in which full recovery has taken several months. Hypermotility and hypersecretion do not appear to return, and the pathway for neurogenic activity, both secretory and motor, remains permanently ablated.

In the presence of hypermotility early pyloric stenosis may escape recognition, since it may do no more than reduce a rapid emptying time to one within normal limits. Reduced gastric tone after vagotomy has occasionally caused such an unsuspected stenosis to come to light.

It has recently been reported by Machella et al. (1947) that normal gastric peristalsis can if necessary be restored by the administration of urethane of β-methyl choline, either by injection or by mouth.

PATHOLOGIST

ESSEX COUNTY HOSPITAL, COLCHESTER

Most of us are familiar with the sight of a nurse ogressing slowly round the hospital ward carrying a ay on which is the customary equipment for taking the tients' temperatures. The purpose of this paper is demonstrate that she may be unwittingly introducing to their mouths a large dose of various pathogenic d non-pathogenic bacteria.

In her textbook of nursing, Pearce[1] describes the ethod of sterilising clinical thermometers as follows:

> "The articles required are: a clinical thermometer standing a jar with cotton-wool at the bottom in order to protect e end of the bulb, the jar being three parts filled with some sinfectant solution, such as 1/20 carbolic, 1/1000 perchloride mercury; a jar containing some either moist or dry wool abs with which to wipe the thermometer after use; a ceiver in which to place the used swabs. It has been found at wiping the thermometer with wool adequately cleanses because the surface is shiny and smooth so that germs do t readily adhere to it. *If there is a sink handy, the thermo*eter is held under running cold water for a few seconds after king it from the patient before wiping it."

She does not say how this procedure should be modified hen the temperatures of 20–30 patients in a general ard are taken. By questioning a number of nurses from arious hospitals, we find that the technique varies onsiderably in detail but conforms to a general pattern.

CURRENT PROCEDURE

A ward of 20–30 patients is supplied with a varying umber of thermometers—usually not more than 5 r 6. These are left standing upright in a small jar t the bottom of which is a small piece of cotton-wool. he jar is more or less full of a fluid which is usually ink and is credited with the property of sterilising the hermometers in a few seconds. When the temperatures *re to* be taken, the nurse places the jar containing the hermometers on a tray, with a small bowl containing otton-wool, and perhaps a bowl of water. The temperaures are taken in batches limited by the number of hermometers available. The thermometers are withrawn from the fluid one by one, dipped into the water, iped with cotton-wool, and placed in the patients' ouths. Probably four or five temperatures are taken t the same time. The thermometers are then removed rom the mouths, dipped in the bowl of water, and eplaced in the coloured fluid. The nurse then passes o the next batch of patients, and the process is repeated. his recurs all round the ward, the same tiny bowl of ater being used, and the thermometers left in the pink fluid for a matter of seconds only between patients. After the round of the ward has been completed, the thermometers are left in the jar until the temperatures are taken again, when the whole process is repeated.

The pink fluid in the bowl containing the thermometers is changed sometimes once in twenty-four hours, but *often* less frequently. The coloured fluid varies in composition; 1 in 20 carbolic acid seems to have been originally advocated, but is by no means always used, because it tends to remove the figures from the thermometers and the patients dislike its taste. Glycerinum thymol co. is commonly used by itself or sometimes mixed with equal parts of 1 in 20 carbolic acid. Some hospitals use a weak solution of 'Dettol' or other antiseptic.

The following tests will show that the procedures outlined above are not only unsound but may be dangerous.

INVESTIGATION OF FLUIDS USED FOR STERILISING THERMOMETERS

Fluid from the thermometer jars from all wards in the hospital was collected into sterile containers at random, without the ward having previous warning, and it was accepted only after one or more thermometer rounds had been undertaken. The results from ward to ward were not therefore strictly comparable. After collection, a loopful of the fluid was plated on 4% horse-blood-agar plates and incubated at 37°C for twenty-four hours. Various colonies were then picked off and the organisms investigated. At the same time as the plating several dilutions of the fluid were made. Plates were poured with these dilutions and with melted nutrient agar. These were incubated at 37°C for forty-eight hours, the colonies counted, and the number of viable organisms per c.cm. of the original fluid estimated. These methods are not very accurate, but some indication of the bacterial contamination is obtained. The results are given in table I.

TABLE I—ORGANISMS GROWN FROM FLUIDS USED FOR STERILISING THERMOMETERS

Ward	Thermometer fluid	Estimated no. of organisms per c.cm.	Organisms developing on blood-agar plate
A	Glyc. thymol co.	7,500,000	*Strep. viridans*, non-hæmolytic streptococcus, micrococcus, *Bact. coli anaerogenes*, Friedlander's bacillus, and a vibrio-like organism
B	Glyc. thymol co.	40,000,000	Micrococcus, *Bact. coli anaerogenes*, Friedlander's bacillus, and a vibrio-like organism
C	Equal parts of glyc. thymol co. and 1/20 phenol	45	*Staph. aureus pyogenes*, a capsulated coliform, *Bact. fæcalis alkaligenes*, and Friedlander's bacillus
D	Glyc. thymol co.	14,000,000	*Staph. albus*, non-hæmolytic streptococcus, *Bact. coli anaerogenes*, and two types of poorly growing gram-negative bacilli
E	Glyc. thymol co.	19,000,000	*Bact. coli anaerogenes*, a vibrio-like organism, and a poorly growing gram-negative bacillus
F	Glyc. thymol co.	900,000	*Staph. albus*, two types of micrococci, *Bact. coli anaerogenes*, Friedlander's bacillus, a vibrio-like organism, and a poorly growing gram-negative bacillus
G	*1/20 phenol*	*0*	None

Much difficulty was experienced in identifying many of the organisms, but they were defined as accurately as possible. It will be seen that the thermometer fluids were grossly contaminated with various pathogenic and non-pathogenic organisms. Since glycerinum thymol co.

of whom have lost their duodenal pain. All, save the most recent, are at work, and all are pleased with the result of the operation. The full effect on the acid secretion is not seen till three months after the operation. All the patients have a well-marked reduction in gastric tonicity. Most show a six-hour residue of barium, and 2, with old periduodenitis and stenosis, have had gross delay in emptying but have nevertheless put on weight and been symptom-free. A gastro-enterostomy may be necessary, however, if the stomach does not regain sufficient tone to drive the meal through the narrowed pylorus, and 7 patients have been submitted to this additional procedure. Appetite has been poor immediately after operation but has returned to normal in a few months. Most patients have remarked on a freedom from their old-standing constipation; and 3 have complained of transient and spontaneously resolving diarrhœa after operation.

The effects of this operation on the titratable "free" acid in the spontaneous night secretion and after insulin and histamine injections are shown in figs. 1, 2, 3, and 4. In patients tested over a year after operation the fall in acidity was found to have become even more marked. Fig. 5 illustrates a result after four months and fig. 6 shows the effect on gastric motility. These curves are selected as representative and a more detailed report will be given elsewhere.

DISCUSSION

The end-results of medical therapy in duodenal ulcer have been reviewed, and it appears that 65% of patients have relapsed within two years, and many have developed acute complications. Though gastro-enterostomy continues to offer a satisfactory answer to the problem of stenosis, provided the gastric acidity is not excessive, even subtotal gastrectomy is not always a satisfactory choice for the highly acid type of ulcer. Apart from an appreciable mortality, there is a growing concern among those who see the late results of gastrectomy. The incidence of stomal ulcer in 2–9% of patients submitted to gastrectomy for duodenal ulcer is disquieting, and an appreciable number continue to have distressing symptoms though no stomal ulcer can be detected radiologically or have symptoms attributable to the gastrectomy itself. For these unfortunate people medical therapy avails little, further and more radical surgery is out of the question, and their last state may be worse than the first.

Per-hiatal vagal resection is advanced at this stage as a surgical measure in the management of duodenal ulcer *for information only, since without a long follow-up* no comparison can be made with the late results of subtotal gastrectomy. Nevertheless we have the authority of Dragstedt (1947) that a four-year follow-up of their vagal-resection patients shows freedom from recurrences. One thing, however, may be asserted with confidence—the fatality-rate of vagal resection will always be less than that of gastrectomy. The procedure, placing as it does little strain on the patient, may be confidently advocated by physicians at an earlier stage in the dyspeptic's life and not only as a last resort after months or years of invalidism and pain.

We do not yet know the long-term results of vagal resection, but it will not spoil the chances of a successful gastrectomy in any patients who may in the future relapse. In other words, vagal resection may be looked on as a reconnaissance in force in the war against duodenal ulcer. Little is lost if, on occasion, it fails, and we still have at our disposal the full-scale attack by gastrectomy with all the risks involved by such large-scale operations. A lasting success by vagal resection is a triumph of physiological strategy, and a failure spells disappointment but not disaster. A failure following gastrectomy, however, is an irretrievable reverse in which much has been sacrificed without hope of withdrawal.

SUMMARY

The incidence of duodenal ulcer is alarmingly high and fast increasing.

Though 80% of ulcers can be healed *medically*, 65% of patients have a recurrence within two years.

The risk of complications is considerable: 1 in 4 or 5 duodenal-ulcer patients bleed or perforate while still young.

Gastrojejunostomy is a failure as a routine procedure. It carries a mortality of about 2% and does not cure more than half the patients.

Gastrectomy is more successful if it is sufficiently radical, but it is also more dangerous. The operative mortality may be 5% in average hands, and the recurrent ulceration-rate 2–9%. A further percentage are not freed of symptoms, and new, symptoms may result from the *operation itself*.

It is claimed that vagal resection is a safe alternative giving promising results.

The rationale of vagal resection is considered.

The operation is described in outline and the advantages of a trans-hiatal section by way of an abdominal approach are presented.

Attention is drawn to the poor results which follow incomplete section, and to the importance of differentiating complete from partial vagotomies by the insulin test.

An interim report is presented on the progress of [illegible] patients submitted to vagotomy or vagal resection.

Continued at foot of next page

ield was determined daily by test-feeds. The test-eeding began on the fifth day, or on the tenth day, and ontinued until the fourteenth day. The subsequent ourse of each lactation was followed up by assessing the aily milk yield from test-feeds done at the end of the ourth, sixth, and twelfth weeks and sixth month of actation.

Hormone preparations were given as follows:

(1) Injections of crude ox anterior-pituitary extract.

(2) Injections of crude ox anterior-pituitary extract plus estrogens by mouth.

(3) Injections of crude ox anterior-pituitary extract plus dried thyroid gland *B.P.* 1932 by mouth.

(4) Injections of crude ox anterior-pituitary extract plus estrogens and dried thyroid gland *B.P.* 1932 by mouth.

The control treatments were as follows:

(1) Breast massage as advocated by Randall (1945).

(2) Injections of physiological saline.

(3) Administration by mouth of a proprietary galactogogue.

Crude Ox Anterior-pituitary Extract.—This was a clear sterile extract prepared as described by Young (1938) and supplied by Glaxo Laboratories Ltd. Its concentration was such that 1 c.cm. contained the material extracted from 250 mg. of fresh ox anterior-pituitary tissue. Each c.cm. possessed prolactin activity (pigeon crop-gland assay) equivalent to about 20 I.U. Folley and Young (1940) showed that this extract was much more highly effective than prolactin in enhancing the milk yield of cows in declining lactation. Folley and Young (1941) suggested that trials of this material should be made in women with failing lactation. Once a day the extract was injected intramuscularly into alternate buttocks in diminishing amounts as follows: 5 c.cm., 5 c.cm., 2 c.cm., 2 c.cm., 1 c.cm. Reactions to the injections were few and were localised at the site of injection.

Œstrogens.—The synthetic material hexœstrol (Boots Ltd.) was used, 1 mg. tablets being given by mouth four times daily during the period of pituitary treatment in two of the groups of patients.

Dried Thyroid Gland.—Tablets gr. 1, made by the pharmacist at St. Thomas's Hospital from powdered thyroid gland *B.P.* 1932, were given by mouth four times daily during the period of pituitary treatment to two groups of patients.

RESULTS

The accompanying table shows the results obtained in the treated cases and in controls. The mean daily milk output before treatment was practically the same in the treated cases and the controls. The increase was also the same during treatment and continued to be the same up to the twenty-eighth day of lactation. Then in the controls the mean daily milk output began to fall, and by the sixth month of lactation it had fallen to 50% below the original level. In the treated cases the fall in the mean daily milk output was delayed until after the sixth week of lactation, and by the sixth month of lactation it was still slightly above the original level. The percentage of infants who were still being breast-fed at six months was almost twice as high among the treated cases as it was among the controls. The reason for this can be seen when the mean daily milk output for each group of cases is examined separately. The controls contain the group with the worst results, whereas the treated cases contain the group with the best results.

Where no treatment was given, the breast-milk had completely dried up in every patient by the third month. The 21 infants were entirely bottle-fed before they were three months old. These were the worst results. Where crude ox anterior-pituitary extract plus dried thyroid gland were given, 38% of the infants were still being breast-fed at six months. These were the best results. It is noteworthy that any form of treatment is better than no treatment at all.

The mean daily milk output was increased by over 100% in the 21 cases treated with crude ox anterior-pituitary extract plus dried thyroid gland. The rate of increase in daily output was no greater than it was among the controls and the other treated cases. The mean daily milk output continued to rise until after the third month of lactation, whereas among the controls and the other treated cases the increase in mean daily milk output ceased about the sixth week of lactation, and the total increase therefore never became as high as 100%. At the sixth month of lactation the cases treated with crude ox anterior-pituitary extract plus dried thyroid gland gave a mean daily milk output well above the mean daily yield before treatment. At the sixth month of lactation most of the controls and the other treated cases gave a mean daily yield of less than the mean daily yield before treatment.

In 7 of the 21 cases treated with crude ox anterior-pituitary extract plus dried thyroid gland, the dried thyroid gland alone was continued after discharge from hospital. Dried thyroid-gland tablets gr. 1 were given daily by mouth until lactation had failed, or until the *fifth month of lactation. The results were no better* than among the patients whose pills had been discontinued on discharge from hospital. In the group of patients given hexœstrol besides crude ox anterior-pituitary extract plus dried thyroid gland the results were no better than in the controls.

MILK YIELD OF WOMEN WITH FAILING LACTATION

Treatment	No. of cases	Mean daily output of milk (oz.) before, during, and after treatment						No. of infants breast-fed 6 months
		5th day	10th day	4th week	6th week	12th week	24th week	
Crude anterior-pituitary extract	16	6	8	8	6	6	5	3 (*18%*)
Crude anterior-pituitary extract plus hexœstrol	13	7	8	7	8	6	4	2 (*15%*)
Crude anterior-pituitary extract plus thyroid	21	6	9	12	13	13	11	8 (*38%*)
Crude anterior-pituitary extract plus hexœstrol plus thyroid	17	5	6	8	7	3	3	2 (*11%*)
Mean for 67 women ..	..	6	8	9	9	7	6	15 (*22%*)
Massage	11	7	9	11	12	9	8	3 (*27%*)
Proprietary galactogogue	15	7	8	9	9	8	2	2 (*13%*)
Saline injections ..	19	5	7	9	9	5	5	4 (*21%*)
No treatment	21	5	7	7	2	0	0	0
Mean for 66 controls ..	..	6	8	9	8	5	4	9 (*13%*)

Further investigations will need to be carried out with dried thyroid gland alone and in combination with hexœstrol, to find out whether the 100% increase in output was caused by the dried thyroid gland, and whether hexœstrol can counteract this effect. From the results shown in the table it seems unlikely that crude ox anterior-pituitary extract is of any value in stimulating deficient lactation in puerperal women.

SUMMARY

In puerperal women with deficient lactation daily injections of crude ox anterior-pituitary extract alone gave no better results than those obtained in controls.

When the crude ox anterior-pituitary extract was reinforced by dried thyroid gland gr. 4 daily by mouth, the increase in output was twice that obtained in the controls, and the increase continued longer.

When hexœstrol was given at the same time as the crude ox anterior-pituitary extract plus dried thyroid

was the usual fluid used, it was decided to test its bactericidal powers. This was done by adding *Staph. pyogenes* (Oxford H strain), *Strep. hæmolyticus* group A, and *Bact. coli* to separate 10 c.cm. amounts of 1 in 3 glycerinum thymol co. (this is the strength dispensed here, but varying dilution occurs on the wards). These were allowed to stand at room temperature and after 1/4, 1, 4, and 24 hours samples were taken and poured with nutrient agar (in the case of streptococci with sterile serum added at the time of the pouring). By this means the numbers of viable organisms were estimated (table II).

TABLE II—BACTERICIDAL POWERS OF GLYCERINUM THYMOL CO.

Organisms	Original no. per c.cm. of glyc. thymol co.	After			
		1/4 hr.	1 hr.	4 hr.	24 hr.
Staph. pyogenes ..	6000	6000	550	4	0
Strep. hæmolyticus	56,000	8000	30	0	0
Bact. coli	3500	3000	3000	2300	240

Phenol has long been known as a powerful antiseptic, and table I shows that diluted 1 in 20 it is much superior to glycerinum thymol co. as an antiseptic, though it may not be effective in the very short time in which thermometers remain in it during a round. Table II shows that glycerinum thymol co. is useless as a bactericidal agent for sterilising thermometers.

DISCUSSION

If the above-described method of taking temperatures is used, thermometers remain in the "sterilising" fluid only a few seconds between one patient and the next. The thermometers are returned repeatedly to this fluid and after each ward round remain there. Thus the fluid in the jars is frequently contaminated and diluted with saliva and the water on the thermometer tray. With an efficient antiseptic, such as 1/20 phenol, the fluid will probably be sterilised between the rounds, but with an inefficient antiseptic, such as glycerinum thymol co., there will be little or no sterilising of the fluid. The passage of bacteria from one patient to the next during a round must depend on the care, efficiency, and knowledge of the nurse and on the potency of the "sterilising" fluid.

Though some antiseptics are bactericidal in a few seconds, these would almost certainly be harmful to the mucosa of the mouth or noxious to the patient. For example, Gardner and Seddon[2] have shown that clean unwashed skin is virtually sterilised with 2% iodine in 70% alcohol in 15–20 sec., but such a solution could hardly be used to sterilise thermometers, because in spite of all possible care a patient would sooner or later have his temperature taken with the fluid still on the thermometer. The use of inefficient antiseptics such as glycerinum thymol co. gives a false feeling of security, and even efficient antiseptics would have their limitations under the present method of taking ward temperatures.

CONCLUSIONS

We suggest that, if ward temperatures are to be taken in the mouth, each patient must be supplied with a separate thermometer which he keeps to himself as long as he stays in hospital. This can be left by the patient's bed in a small jar containing an antiseptic solution. When he leaves hospital, his thermometer must be properly sterilised before being used again. This can be done by washing the thermometer in running cold water, drying it, and placing it in some effective antiseptic for a time long enough to allow the antiseptic to act.

HORMONAL TREATMENT OF DEFICIENT LACTATION

RESULTS WITH CRUDE ANTERIOR-PITUITARY EXTRACT

MARGARET ROBINSON *
M.D. Belf., D.P.H.
RESEARCH ASSISTANT, MEDICAL RESEARCH COUNCIL

IN an extensive study of failing lactation in women (Robinson 1943) no obvious reason was found for the failure in at least 40% of the cases examined. It seemed that an endocrine dysfunction might be responsible, but no clinical signs of this were discovered. On the suggestion of Prof. F. G. Young and with the support of the Medical Research Council and the clinical advice of Mr. J. M. Wyatt, the influence of various hormone preparations on failing lactation was investigated. The present report deals with the results of treatment, during the puerperium, with crude anterior-pituitary extract, administered either alone or with other substances.

METHOD

Assessment of Milk Yield.—From the fifth to the thirteenth day of the puerperium the infants were test fed at every feed. The sum of all the test-feeds done in one day gave the total daily output of milk and was calculated for each day of the puerperium. After discharge from hospital the mothers reported for test-feeding when their infants were four weeks, six weeks, twelve weeks, and six months old. Two consecutive test-feeds were done on each of these days. The times of the feeds were either 10 A.M. and 2 P.M., or 12 NOON and 3 P.M. The average of these two test-feeds was multiplied by five or six, according to whether the infant was being fed four-hourly or three-hourly. This gave the total daily output of milk in the fourth, sixth, and twelfth weeks and sixth month of lactation.

Criteria of Failure to Establish Lactation in the Puerperium.—In 500 untreated lactations the infants were test-fed each day during the puerperium and were followed up during the next six months. Failure before the sixth month of lactation was rare where the milk output on the fifth day of the puerperium had been at least 10 oz., and on the tenth day at least 16 oz., whereas nearly all the failures occurring in the first three months of lactation had had a milk output of less than 10 oz. on the fifth day of the puerperium, or of less than 16 oz. on the tenth day. Therefore an output of at least 10 oz. on the fifth day of the puerperium and of 16 oz. on the tenth day was taken as the standard of establishment of lactation in the puerperium.

TREATMENT

Four different types of hormone treatment were used and three different types of non-hormonal treatment were used to provide controls. As a further control, an eighth group of patients was left untreated. In all, 126 patients were investigated, this number being randomly distributed among the eight groups indicated above. To avoid reactions to the protein in the crude ox anterior-pituitary extract, injections of this material were not given to patients with a family history of allergy.

All infants were test-fed on their fifth and tenth days. If, according to the criteria mentioned above, there was a failure to establish lactation on either of these days, experimental or control treatment was given daily until the thirteenth day, except in the case of injections, which were only given for five consecutive days. On the average, treatment began on the seventh day of the puerperium and ended on the thirteenth day. The milk he amounts thus gained are trivial, and the appeals ster the idea that streptomycin is a cure.

B.C.G. VACCINATION

Dr. Esmond Ray Long, Philadelphia, U.S.A., said hat both in Britain and the United States the attitude o B.C.G. has been cautious because of a correct insistence n statistical analysis, which in early trials was neglected, d also because good progress has been made with other methods. A controlled study initiated in the U.S.A. in 935 among 3000 young people, aged from 1 to 20 years, confirmed earlier estimates from other countries that the ubsequent risk of death from tuberculosis is six or seven mes less in the vaccinated than in the unvaccinated; nd figures for the attack-rates were even more impresve. Results after ten years were still better than after ix years. It would be illogical to attempt mass immuniation in the United States, for the national rate of uberculosis has recently been estimated as only 37·4 er 100,000; but selected groups should be vaccinated. n some countries, however, B.C.G. is an almost essential art of the anti-tuberculosis campaign.

Dr. K. N. Irvine advanced a plan for the B.C.G. accination of all negative tuberculin-reactors among ontacts. In countries where the populations are for the irst time being exposed to tuberculosis, a simplified cheme for mass vaccination should be adopted. The accine can at present be kept for only ten days; but Russian experiments in drying the vaccine are successul it will in future be preserved longer; and it will then e possible to test each batch before using it clinically.

THE VOLE BACILLUS

Dr. A. Q. Wells, in a paper read for him by Dr. J. H. Harley Williams, expressed his belief in the safety of accination with the vole bacillus. A single intradermal njection sometimes gives rise to a small ulcer, as with B.C.G., but this is comparatively innocuous. The interretation of results is difficult; but it is agreed that ensitivity to tuberculin after vaccination with the vole acillus is greater and occurs earlier than after B.C.G. The vole bacillus is a naturally occurring infecting gent in voles; and, unlike B.C.G., it can be maintained t a constant virulence by animal inoculation. A properly controlled study of the vole bacillus should be ndertaken, with regard to these essentials: (1) the ncidence of tuberculosis in the communities to be tudied should be high, and the communities should be elatively stable; (2) there must be strictly impartial division of the tuberculin-negative reactors into vaccinated and unvaccinated groups; (3) the vaccinated and unvaccinated groups must be as nearly as possible equal n number and in age, sex, race, risk of infection, and socio-economic status; (4) vaccinated and unvaccinated groups must be continuously supervised for at least five years; and (5) the numbers in each group must be large enough for statistical analysis.

STREPTOMYCIN

Dr. H. C. Hinshaw, vice-president of the National Tuberculosis Association, U.S.A., said that streptomycin modifies some forms of tuberculosis for a limited and possibly predictable time. Its limitations are imposed by the pathology of the disease and by the characteristics of the tubercle bacillus. The committee on therapy of the American Trudeau Society recently reported that streptomycin should be given in: (1) tuberculous meningitis, where the chance of complete clinical remission is big enough to justify its employment in all cases (a few, said Dr. Hinshaw, have recovered completely); (2) hæmatogenous miliary tuberculosis (for this is the only remedy, and there is reason for hoping that it may reduce the mortality from 100% to 50%); (3) tuberculous laryngitis; (4) progressive ulcerative lesions in the tracheobronchial tree; (5) extensive, progressive, pulmonary tuberculosis and tuberculous pneumonia, but not early fibroid or fibrocaseous pulmonary tuberculosis or chronic tuberculous empyema; (6) acute ulcerative tuberculous enteritis; and (7) sinuses from tuberculous lymphadenitis. Its effectiveness against other forms of tuberculosis, such as those affecting the genito-urinary tract, bones, joints, and skin, has yet to be assessed. The frequency and severity of vestibular disturbances following streptomycin have, said Dr. Hinshaw, been exaggerated; he knows of no case where any persistent disturbance is detectable except by fine tests: and with purer streptomycin the frequency of even this slight disturbance may decrease. In 1000 cases none with loss of hearing has been observed except among those who have had tuberculous meningitis. However, "streptomycin should be avoided where other treatments are available. I know of one case who two years ago at his own request was treated with streptomycin for minimal disease, and now has extensive progressive disease resistant to the drug." Cases for treatment must be wisely chosen; and the risk of exacerbation at the end of treatment must be acknowledged by keeping the patient at rest in bed. Streptomycin will possibly supplement, but will never supplant, other forms of treatment.

Dr. H. S. Willis, Northville, Michigan, said that in the United States a coördinated study has already been made of more than 1000 cases treated with streptomycin, while another 600 are now being studied; and probably 700 have been treated independently. Under the plan for a coördinated investigation individual workers are free to publish their results; but they are pledged to adhere to certain schedules. "Here is a drug which has made the grade in a few types of tuberculosis, where it now stands as a 'must'; but the large majority of cases are not susceptible to it."

Dr. S. A. Waksman, U.S.A., said that he and his colleagues originally investigated streptomycin for its power to combat the gram-negative organisms which are unaffected by penicillin. To their surprise laboratory tests suggested that it was effective against the tubercle bacillus; and this was confirmed by Dr. Hinshaw and his associates, to whom early samples were sent. "Streptomycin may not be the final answer—I hope it is not—but it has pointed the way to other agents."

Dr. P. M. D'Arcy Hart, winding up the discussion, said that at the end of 1946 the Medical Research Council received from the United States 50 kg. of streptomycin—enough for 200–250 cases. The council established two committees to investigate streptomycin—one in relation to tuberculosis, under the chairmanship of Dr. Geoffrey Marshall, and the other in relation to other conditions, under the chairmanship of Sir Alexander Fleming, F.R.S. There are now eight centres for the treatment of meningitis with streptomycin; and the results will be published as a piece of group-research. Some cases of miliary and of pulmonary tuberculosis are also being treated. The Ministry of Health, he said, is proceeding with the production of B.C.G. vaccine. The danger of using the vaccine is that it may lead to a slackening of other measures against tuberculosis.

Reviews of Books

Handbook of Correctional Psychology

Editors: Robert M. Lindner, Ph.D.; Robert V. Seliger, M.D. New York: Philosophical Library. 1947. Pp. 691. $10.

Correctional psychology is described in the editors' preface as "a branch of applied medical art and science which properly restricts itself to the understanding and treatment of individuals under conditions of detention." Their book "includes only material which will be practical, applicable, and of immediate value" and is presented as a "source book to which the institutional psychiatrist, psychologist, physician, caseworker and administrator can turn for guidance in the performance of his functions." If the reader accepts this definition he cannot reasonably complain that there is relatively little psychology in this collection of articles; but he may wonder whether it is possible to compile a "source book" which contains only practical material.

The 46 contributors vary widely in their approach; there is no index; and the arrangement does not indicate which chapters are meant for which of the five different classes of reader. Also the balance of contributions is open to criticism.

Chapters are devoted to E.N.T., dental, acute medical, and venereal practice, and to gastric neuroses, sedation, electric gland, the results were no better than those shown by the controls.

It is therefore possible that dried thyroid gland may stimulate lactation in the puerperium, and that hexœstrol may counteract its action.

In the cases treated with crude ox anterior-pituitary extract plus dried thyroid gland the full effect of the stimulation of lactation seemed to be obtained by treatment in the puerperium only.

The continuation of the dried thyroid gland alone, after discharge from hospital, seems to be unnecessary.

I wish to thank Mr. J. M. Wyatt, F.R.C.S., F.R.C.O.G., Mr. A. J. Wrigley, F.R.C.S., and Prof. F. G. Young, D.SC., for their help and criticism; and the nursing staff of St. Thomas's Hospital for their coöperation. I am indebted to the Medical Research Council for their support and to Glaxo Laboratories Ltd. for the materials used in some of the experiments.

A SWALLOWED PIN RETAINED IN THE APPENDIX

J. SCHOLEFIELD
M.B. Leeds, F.R.C.S.
SURGEON, WEST MIDDLESEX COUNTY HOSPITAL

A COMMON history at any large hospital is that the patient has swallowed a foreign body. If this reaches the stomach it is usually passed spontaneously without need of operation. The pylorus, the "hairpin" bends of the duodenum, and the ileocæcal region are the most commonly reported points of impaction.

Many different objects small enough to enter from the cæcum have been retained in the appendix; but most of the published reports are concerned with those responsible for acute symptoms, and I can find few instances where operation was necessary for removal of a retained foreign body which did not cause any complications.

At one time foreign bodies were thought to be a common cause of acute appendicitis, but nowadays such a cause is considered rare. They still sometimes cause acute appendicitis from erosion of the mucosa, with entrance of organisms into the appendix wall, or they may act as a nucleus for a fæcolith, with the eventual onset of classical obstructive appendicitis. Sharp-pointed foreign bodies may perforate the wall and cause peritonitis, or a more gradual penetration may lead to a local abscess. They may lie dormant for years, but always remain a potential menace to the host.

CASE-RECORD

A boy, aged 13 years, was seen at the West Middlesex County Hospital on Oct. 11, 1942, with a history of having accidentally swallowed a pin at 3.15 that afternoon.

Radiography revealed a large pin in the central abdomen, and the patient was admitted to hospital. Next day radiography showed the pin to be in the right iliac fossa, and repeated radiography in the next six weeks indicated no real progress of the pin, though there were slight variations in its position. The patient during this period had no symptoms, and physical signs were completely lacking.

Retention of the pin at the ileocæcal valve was diagnosed; and, in view of the lack of progress and the danger of slow perforation, I decided to operate.

On Nov. 23 a small right paramedian incision was made, and the first structure to present in the peritoneal cavity was the appendix containing the pin, whose glass head was resting at the tip of the appendix.

A simple appendicectomy completed the operation. When the appendix was opened the pin was found to be 2½ in. long, with a glass head the size of a small pea. The mucosa appeared normal.

On reviewing the case after operation, I felt that retention in the appendix should have been surmised. Earlier intervention might also have been considered, but a waiting policy in these cases had, in my previous experience, been invariably successful.

Medical Societies

COMMONWEALTH TUBERCULOSIS CONFERENCE

DELEGATES to the Commonwealth and Empire Health and Tuberculosis Conference, convened by the National Association for the Prevention of Tuberculosis in the Central Hall, Westminster, on July 8, 9, and 10, were addressed by Mr. ANEURIN BEVAN, the Minister of Health. Speaking of the National Health Service Act and its effect on tuberculosis work, Mr. Bevan pointed out that the increase in tuberculosis notifications is merely a reflexion of more accurate diagnosis and earlier recognition. The resulting earlier treatment is responsible for the decline in mortality. We could do much more for the early cases but for the many sanatorium beds standing idle because of lack of nurses and domestic staff. We have more nurses than ever before, but a larger number of people are going to hospitals and sanatoria for help; hence the need for still more nurses. In the National Health Service the sanatoria will retain their identities, because there is a great moral reserve in tradition. There will be an integration on the institutional side of all the tuberculosis institutions and the regional boards, but on the personal side responsibility will rest with the local health authority. Some will object to what they will call a dichotomy in the service, but the Ministry hope that the tuberculosis officers will be joint appointments with the local health authority, so there will be a link at the executive point, where the actual work is being done. The winding-up of the poor-law system will have an important bearing on tuberculosis treatment. The benefit paid under National Health Insurance was too low to encourage tuberculous people to undergo treatment in time, and the special allowances introduced during the war had the grave and cruel disadvantage that they were withdrawn if the patient was incurable. Under the new scheme this disability will be removed because the benefits paid will be much higher. The Assistance Board will also give additional help, with special provisions, to tuberculous patients. Patients will then receive help without any stigma attaching to it. *We are hoping, by the provision* of spacious well-lit homes, by supplying extra nourishment for children, by looking after mothers and babies, by developing social services generally, and by facilitating earlier diagnosis and earlier treatment, to ensure a continued fall in tuberculosis mortality.

On July 9, the second day of the conference, a discussion was held, under the chairmanship of Prof. S. LYLE CUMMINS, on

Specific Measures in the Prevention and Treatment of Tuberculosis

In an introductory speech Prof. W. H. TYTLER referred to the proved safety of B.C.G. vaccine; but its efficiency is, he said, less easily ascertained. Vaccination is less effective among populations with a low than in those with a high primitive mortality from tuberculosis; perhaps this is because in low-mortality populations those who, despite vaccination, have persistently poor resistance represent the residue of family stocks with poor natural immunity. The attitude to B.C.G. has been one of apathy, possibly because people have been unconvinced of its real advantage. There is, however, growing enthusiasm for its use among uninfected and exposed young adults. Vaccination with the vole bacillus may offer the advantage of continuing immunity; but B.C.G. has been well tried and should not be discarded until the superiority of the vole-bacillus vaccine has been proved with certainty. It is doubtful if streptomycin will cure advanced tuberculosis; and "I should like to protest against broadcast appeals for streptomycin."

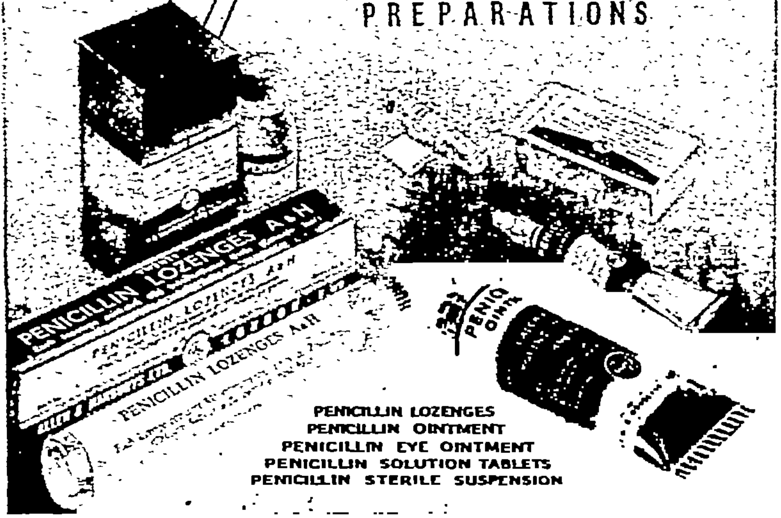
PREPARATIONS



PENICILLIN LOZENGES
PENICILLIN OINTMENT
PENICILLIN EYE OINTMENT
PENICILLIN SOLUTION TABLETS
PENICILLIN STERILE SUSPENSION

Rational Penicillin Packaging

A & H Penicillin preparations are packed in containers chosen

★ to meet the needs of individual treatment prescribed by the physician;

★ to afford protection from contamination during use, thus ensuring maximum therapeutic effect;

★ to eliminate waste.

Penicillin Lozenges A & H each contain 500 units of penicillin (calcium salt); tubes of 20 lozenges.

Penicillin Ointment contains in each gramme of anhydrous base 500 units of penicillin (calcium salt); tubes of 1 oz.

Penicillin Eye Ointment contains in each gramme of anhydrous base 1,000 units of penicillin (calcium salt); tubes of 5 grammes.

Sterile Penicillin Suspension (Oily Injection of Penicillin) contains 125,000 units of penicillin (calcium salt) per c.c.; rubber-capped vials of 10 c.c.

Penicillin Solution Tablets contain 12,500 units of penicillin (calcium salt) per tablet; for preparing solutions for external use only; tubes of 8 tablets.

shock, psychotherapy, and puberty, though these matters are common to medical practice in all organised communities. In those describing the technique of electro-encephalography, hypno-analysis, psychometric procedure, diagnosis and training of mental defectives the detail is too great for the casual reader but insufficient for a practitioner. On the other hand, practical mental hygiene and specific methods of preventing maladjustments are disposed of in two pages.

Articles on the treatment of juvenile delinquency, on municipal courts, and on the classification clinic in a big penal institution show the English reader how much can be achieved by the intelligent application of psychiatric principles to the handling of crime. Other chapters indicate varying stages of progress in the United States, as shown in a bitter attack on the legal attitude to sex offenders, and a plea for "some form of training for personnel (staff) in juvenile delinquency institutions." That this variation extends to medical men is suggested by a warning to young doctors entering the prison service against accepting bribes from inmates!

Certain attitudes of contributors are surprising: delinquency is said to arise out of divergent viewpoints in society; ruthlessness is the automatic sequel of lack of love in the home. Consistently enough, the same writer wants preventive schools to supervise the delinquent child's "every moment," and advocates compulsory work, as "the only way to cure juvenile vagrancy." A delinquent needs teaching "how to withstand the environment to which he will return"; and another contributor advocates (admittedly with diffidence) the use of "specially trained prostitutes" in the treatment of exhibitionists, though his own description of the character of prostitutes suggests that they might not prove easy to train.

Chapters devoted to psychopathic personality are frankly disappointing; because of insufficient coördination they do little to clear up the confusion reigning in that field. The psycho-analytical contributions, of which there are several, are more impressive because they show evidence of original thought and are noticeably modest and reasonable in their assertions. A plea for the public financing of the planned investigation of 500 criminals by 50 trained psycho-analysts is both timely and reasonable.

Much time and care has obviously gone into the preparation of this volume, and our criticisms arise from its attempt to achieve an unattainable and perhaps unworthy object—to be a figurative departmental store in which serious workers may obtain their professional tools. It does, however, show how much needs to be done if Britain is not to be left far behind the United States in dealing with antisocial behaviour.

Sick Children: Diagnosis and Treatment

(6th ed.) DONALD PATERSON, B.A. Manitoba, M.D. Edin., F.R.C.P., physician to the Hospital for Sick Children, Great Ormond Street. London: Cassell. 1947. Pp. 455. 16*s*.

THIS well-known book is comprehensive and detailed, but still of convenient size. This edition looks like the mixture as before, but many portions have been revised and several have been rewritten. Most pædiatricians use larger doses of the sulphonamides than those recommended by Dr. Paterson for young infants. In general however the book is up to date and reliable. It is not very easy to read consecutively, but is a good compact reference book. The index is well made. Hæmorrhagic disease of the newborn has to be sought as "hypoprothrombinæmia" or by way of "vitamin K," but such defects are uncommon.

Treatment of Bronchial Asthma

VINCENT J. DERBES, M.D., instructor in medicine and in preventive medicine, Tulane University of Louisiana; HUGO TRISTRAM ENGELHARDT, M.D., F.A.C.P., instructor in clinical medicine, Baylor University College of Medicine, Houston, Texas. London: J. B. Lippincott. 1946. Pp. 466. 48*s*.

THIS book by the authors and nineteen other contributors gives a clear account of the basic factors in the production of asthma, and then discusses the clinical treatment from these fundamentals. The important facts of anatomy and physiology are given concisely, and the chapter on the experimental and theoretical siderations of immunology is well illustrated and this difficult subject fairly intelligible. Various of modern treatment are considered under [illegible] headings. The "desensitisation" type of [illegible] is perhaps emphasised too much at the expense physical treatment—athletic training, games, and tory exercises—which some believe to be more [illegible] especially for young asthmatics. The chapter on [illegible] treatment carries some good anatomical illustrations with details of operative technique; but more facts be welcome about the clinical results after five [illegible] We really need to know the ultimate fate of a big group of asthmatics treated by specific means, as compared with a control group treated palliatively.

Notes on Essential Factory First Aid (Croydon Couldrey & Co. 1946. Pp. 16. 1*s*.).—Sir Ernest Cowell has produced a series of short lecture notes on first-aid, designed to be read in conjunction with the standard first-aid books and containing some points which have not reached them. As "bread and butter" first-aid, the notes are brief, clear, and full of common sense, but they hardly justify the title of "factory first-aid." No mention is made of the many conditions peculiar to factories for which first-aid treatment is necessary. For instance, a factory first-aid worker should be told how to deal with a scalping accident, how to get an electrocuted worker off a crane-track or a gassed one from a soaking pit; what to do, if anything, for a cyanosed chemical worker, and what is the first-aid treatment of cyanide poisoning. He will want to know what to do when acids, alkalis or other chemicals splash into eyes, and whether there is anything to be done for a welder who gets "eye flash." Again, what should be the first-aid treatment for a burn by boiling pitch which sticks to the skin? Each industry has its special health risks and types of accidents, and no book dealing with factory first-aid should omit to mention them.

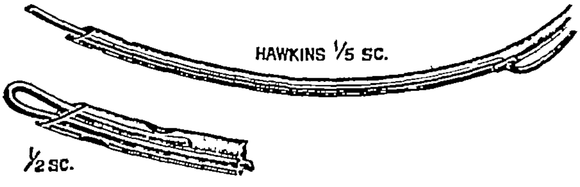
New Inventions

FLUSHING CATHETER FOR USE AFTER RETRO-PUBIC PROSTATECTOMY

THE instrument illustrated here is made of plastic and consists of a size 26 whistle-tipped catheter with a narrow tube let into the side and lying free in the lumen to project beyond the terminal opening.

It is sterilised by boiling and passed with the projecting tube turned back (see inset diagram) through the urethra into the prostatic bed; the end is then pulled out and the catheter guided into the bladder neck.

After suture of the prostatic capsule 4 ounces of citrate solution is instilled into the bladder and both tubes of the catheter spigoted. On the patient's return to the ward the narrow tube is connected through a drip interrupter to a reservoir and the large end to a bottle under the bed. Citrate solution (2 pints), followed by normal saline or saline and sulphanilamide solution, is dripped through continuously for the next 48 hours. This continuous irrigation prevents clots accumulating in the bladder, and the urine rapidly becomes clear.



The object of the small tube lying free in the catheter is to facilitate cleaning; it could also be withdrawn an emergency. The projection of the small tube b[illegible] the catheter end ensures irrigation of the bladder and [illegible] of the catheter only.

I have used this instrument and its rubber prototype with complete satisfaction on many occasions.

The catheter is made by Messrs. A. L. Hawkins & Co. Ltd. of London.

Vagal Resection for Peptic Ulcer

It is natural for a sick man to shrink from a surgical eration if medicine can cure him, and the sufferer om peptic ulceration is usually wise to explore the ysician's resources before undergoing an operation. ut where medical treatment has failed surgery will ten restore the patient to health. The results of eration nevertheless fall considerably short of erfection, partly because surgery carries an apprecible mortality, and partly because though it will cure n ulcer it may fail to prevent a recurrence. Many ifferent operative techniques have been tried in ttempts to remedy these defects—to combine safety ith maximum reduction of the abnormal acidity and uantity of the gastric juice, which are associated with eptic ulcer. The latest of these techniques is resection the vagus nerves, and first-reports suggest that this ay be a major advance.

The conception of vagal resection as a treatment for ptic ulcer must be nearly as old as the knowledge the vagi are responsible for the psychic flow of astric juice, but it was not until the work and writings f L. R. Dragstedt and his colleagues drew attention it that the idea caught on. Dragstedt and Owens[1] howed that, whereas the normal man ceases to secrete ic juice when he is asleep, the ulcer patient coninues to do so throughout the night. This juice, nprovoked by food, must be a psychic flow, mediated hrough the vagi; and, undiluted by food, it is the rime factor in causing ulceration, particularly when t is hurried into the duodenum by a hypermotile tomach. Dragstedt hoped in particular to decrease he night flow by vagal denervation of the stomach, nd the excellent results of his procedure have been ttested by many workers. The immediate effects of ection of the vagi are to reduce the quantity and cidity of the gastric juice and the motility of the tomach, and, though all three return with the passage f time to nearly normal, night secretion and hypermotility are permanently abolished so far as can be udged in the limited time so far available for follow-up f the patients. Section of the vagus probably does more than this. There is evidence (some of it contraictory) that it cuts the afferent pathway for stomach nd duodenal pain, that it abolishes the spasm of the uodenum which many think is the origin of ulcer ain, and that it severs the nervous connexion between he stomach and the cerebrum. This last may be the ey to the success of vagal resection. The evidence or it is the finding by Dragstedt[2] that in man nger or nervous tension immediately and greatly ncreases the amount of gastric juice which can be ecovered from an indwelling Ryle's tube, an effect hich is abolished by section of the vagi. Wolf[3] as amplified these observations by showing that vagal resection in man abolishes those vascular responses of the stomach to emotion which he and Wolff[4] described in their classical monograph.

The indication for vagal resection is long-standing peptic ulceration which has resisted medical treatment. Duodenal ulcers constitute the majority of cases hitherto reported, and typical ulcer patients, who can relate recrudescence of their symptoms to anxiety or stress, are said to do very well. If pyloric stenosis is present, a gastro-enterostomy or pyloroplasty is an essential addition to the operation; one could hardly expect a physiological operation on the vagi to correct anatomical obstruction by old fibrosis. In cases of gastric ulcer vagal resection leads to healing, though some surgeons believe that it should be combined with partial gastrectomy. Gastrojejunal ulceration after gastro-enterostomy or gastrectomy responds well to vagal resection, according to reports, and those who have had to make a second attack on a stomal ulcer by orthodox techniques will welcome a method of side-stepping its difficulties and perils. Patients who do not do well are those with a bad emotional history, in whom dyspeptic pain is one of many symptoms. One need scarcely add that patients in the throes of an acute gastroduodenal hæmorrhage are not suited to vagal resection; but a history of hæmatemesis or melæna is no bar.

The technique of vagal resection is not unduly difficult. The nerves are attacked in the region of the diaphragm. Unfortunately their anatomy is variable at this point. They may appear as two stout nerves, one anterior and one posterior to the œsophagus, or they may be plexiform. Twigs moreover may leave the vagi well above the diaphragm to enter the œsophageal musculature and run therein to the stomach. These anatomical peculiarities have been described by Mitchell[5] and with special reference to vagus resection by Bradley and colleagues[6] and by Miller and Davis[7] To secure complete vagal denervation of the stomach not less than an inch of the nerves or the plexus should be removed. The approach to this task may be either through the chest or through the abdomen. The thoracic approach has the great advantage that in the absence of pleural adhesions it is easy and total vagal interruption is fairly certain. The greater part of the eighth rib on one or other side is resected, the pleura opened, the pulmonary ligament divided, and the lower inch of the œsophagus mobilised and rotated on a tape as far as is necessary for the identification and resection of the vagal apparatus. This chest approach however suffers from the disadvantages that a thoracotomy is more perilous than a laparotomy, that pleural effusion and pain in the chest scar often occur, and that the stomach and duodenum are not open to direct inspection. The abdominal approach is technically more difficult, because the surgeon has to work under the high concavity of the diaphragm. The vagi can be sectioned but the cardinal difficulty is to remove a length of all the vagal fibres traversing the œsophageal hiatus. This difficulty can be overcome by the method described by Crile,[8] and in this issue Orr and

WHOOPING COUGH

DIPHTHERIA

● The success of the campaign for diphtheria immunisation focuses attention upon the gravity of the figures relating to whooping cough. For this reason and for the convenience of *simultaneous* prophylaxis against both diseases, Glaxo Laboratories present the new preparation of *combined* antigens—Diphtheria Prophylactic A.P.T. plus Pertussis Vaccine (Alum-Precipitated). This condenses prophylaxis into one course of three injections (0.5 cc., 0.5 cc., and 1.0 cc.) at monthly intervals. Each cc. contains, in equal proportions, the customary Diphtheria A.P.T. (at least Lf 25) and 20,000 million H. pertussis alum-precipitated.

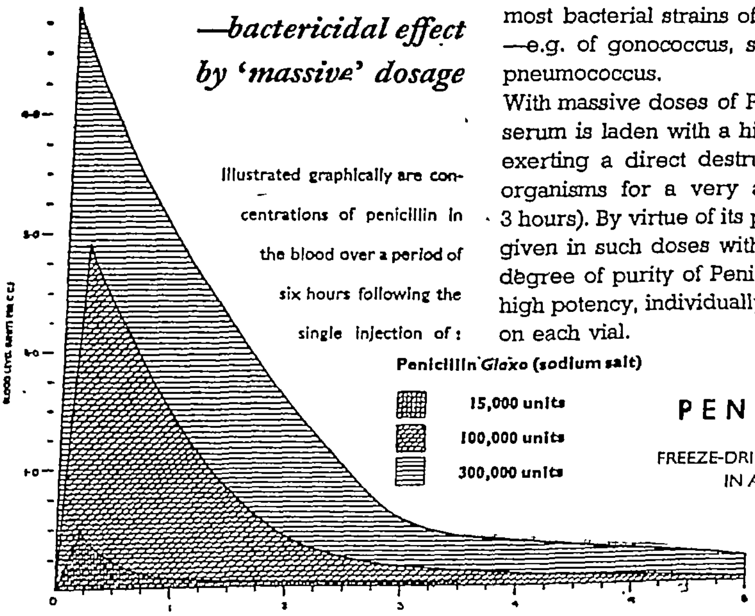
PENICILLIN *Glaxo*

—bactericidal effect by 'massive' dosage

Illustrated graphically are concentrations of penicillin in the blood over a period of six hours following the single injection of:



At low serum levels penicillin exerts a bacteriostatic effect. At higher levels a direct bactericidal effect is achieved, beginning at perhaps 0.5 to 1 unit per cc. for most bacterial strains of ordinary penicillin-sensitivity—e.g. of gonococcus, staphylococcus, streptococcus, pneumococcus.

With massive doses of Penicillin *Glaxo*, therefore, the serum is laden with a high concentration of penicillin exerting a direct destructive effect on the invading organisms for a very appreciable time (from 1 to 3 hours). By virtue of its purity, Penicillin *Glaxo* can be given in such doses without pain or side effects. The degree of purity of Penicillin *Glaxo* is reflected in its high potency, individually stated in units per milligram on each vial.

PENICILLIN Glaxo

FREEZE-DRIED SODIUM SALT FOR INJECTION
IN AQUEOUS SOLUTION

In vials containing 100,000 units, 200,000 units; 500,000 units and 1,000,000 (1 mega) units per vial.

GLAXO LABORATORIES, LTD., GREENFORD, MIDDLESEX BYRon 3434 ings from all this: wherever they are placed—ne, infirmary, cottage, institution, or hospital rd—and whatever their disabilities—crippling umatism, incontinence, chronic bronchitis, even cer—old people can be content and cheerful if y are given the chance; and whether or not they the chance depends on the character, insight, and ermination of those in charge of them. These are ple of many sorts: medical officers of health, blic-assistance officers, housing managers, visiting eral practitioners, wardens, masters, matrons, rses, assistant nurses, orderlies, even ward-maids—y one of whom may be an arbiter of destiny for old and helpless. Individual kindness from any mber of the hierarchy counts for much: a friendly rd-maid can partly compensate for an unimaginative ster. But a uniformly happy atmosphere in wards, stitutions, and homes is achieved only when the ople at the top are keen and interested and inspire like enthusiasm in the rest of the staff. Nurses e conditioned by their training to follow the lead doctors: and a bored and apathetic doctor who inks the old and infirm not worth treating usually akes his nurses bored and casual too. This is the ore likely to happen where nurses are scarce and handful of girls and women have the heavy task of ring for more old people than they can possibly anage. The nursing of the old is skilled, exacting, d absorbing work, as nurses at the West Middlesex ospital have shown; but it can only be done operly where there are enough people to do it. several of the hospitals visited, shortage of nurses as making skilled work difficult. A striking contrast as seen in the infirmaries of Gloucestershire, where e part-time nursing scheme has been an unqualified ccess. Many other local authorities, encouraged y the Ministry of Health, have launched part-time hemes; and though some of these have been based ccessfully on Gloucestershire experience, others re not achieving the same brilliant result. At is critical moment failure cannot be condoned. nless enough good nurses can be won to the care f the chronic sick the able plan proposed by the ritish Medical Association committee[2] will fall to the round. This problem stands apart from the nursing isis as a whole, for we have been shown that it can e handled separately and with outstanding success. here there are special local difficulties our national putation for finding a way round must justify itself. he only difficulties likely to prove insuperable are ck of will and ability in those entrusted with running e schemes; such people should be superseded.

Dr. MARJORY WARREN, Dr. L. Z. COSIN, and Dr. REVOR H. HOWELL, working in three different stitutions, have shown the revolution in atmosphere nd tempo which active medical and surgical treatment bring to infirmary wards. Patients no longer ake to sluggish days, when meal-times make the nly breaks and their own boredom and ill-humour nfect the hard-pressed nursing staff. They are eager, xpectant, keen to get on; or, if treatment can do o more for them, they are occupied, gossiping, and lert. The same change in spirit is found in the loucestershire infirmaries where the relays of nurses, fresh from their own family interests, unfatigued, and pleased with their opportunity for service, bring the old people news from the outside world. Incontinence, that outstanding cause of mental and physical misery for the old and infirm, responds to training far more often than is usually supposed, as nurses at the West Middlesex Hospital and St. Helier, Carshalton, have fully demonstrated; while a new method of medical treatment devised by Dr. THOMAS WILSON is proving its value at St. John's, Battersea. Physiotherapy and occupational therapy can easily be extended to old people living at home, as St. Helier has shown: three groups of old people daily are brought to the hospital in a Ford brake and taken home again after treatment. Birmingham has made it clear that the large institution need not carry on the gloomy traditions of its type, and that even ancient, bleak, and unsuitable buildings can be a centre of pleasant community life if managed with imagination.

Homes for small groups are seen at their best in the Hill Homes, Highgate, the homes of the Worthing Council of Social Service, and the hostel at Aberdeen. Old people like the intimate atmosphere, the smaller rooms, and the friendliness of such homes, and the Ministry of Health[3] is encouraging local authorities to acquire houses suitable for conversion into homes for 25–35 residents, and to run them on the liberal lines which the voluntary societies have developed. Thanks to representations to the Assistance Board by the National Old People's Welfare Committee, a supplementary pensioner now receives 37*s.* weekly, which means that, once established, such small homes can be self-supporting: the old people can pay for their maintenance and still have something over for pocket-money. It is a great misfortune that those admitted to public-assistance institutions are not allowed to retain their pensions and to pay for themselves in the same way. A "charity institution" is still, for them, a symbol of degradation; to pay their way would mean a return of self-respect. It is believed that the Government, which has shown itself sympathetic with this view, may introduce more enlightened practice either by regulation under the National Insurance Act or by fresh legislation in the forthcoming National Assistance Bill. For healthy independent old people, bungalows and almshouses, such as those at Trowbridge and Devizes, are specially suitable. Estates containing houses or flats for the elderly would gain greatly if they also carried a nursing and home-help service, for, as Lord AMULREE has repeatedly pointed out, the line between health and sickness in old age is exceedingly fine. The Linen and Woollen Drapers' Institution, with its properly staffed nursing-home set among the cottages of the estate, has shown what can be done.

Since our articles are by no means comprehensive, it seems proper to refer here to the work of the National Old People's Welfare Committee, which brings together the national organisations and pools their experience on the needs of old people and on measures designed for their well-being. Some 158 local committees are now active, and have already established homes for about 1000 old people, besides encouraging the work of other voluntary bodies in this field. They

Report (1947) of the Committee on the Care and Treatment of the Elderly and Infirm. *Brit. med. J.* June 21, supplement; and see *Lancet*, June 21, p. 874.

[3] Circular no. 49/47.

JOHNSON have briefly indicated their method of enlarging the œsophageal hiatus to reach the posterior mediastinum. Once a satisfactory vagal resection has been accomplished all the advantages are with the abdominal approach. Mechanical defects such as pyloric stenosis can be remedied and gastric carcinomata or gall-bladder disease will not be overlooked. It seems likely that the thoracic approach will remain useful for patients who have already undergone radical surgery of a more usual kind for their peptic ulcer and have developed gastrojejunal ulceration. Here the pathology has already been verified, and exposure from below, difficult enough in the normal abdomen, may be impossible when the anatomy is distorted and obscured by adhesions.

There is general agreement that most patients lose their symptoms and most ulcers heal after vagal resection. THOMPSON and JAMES, who reported 4 cases in these columns last week (p. 44), found that all the patients were symptomatically relieved and their gastric acidity showed a substantial fall. In this issue ORR and JOHNSON report 50 cases. The first 15, in which a subdiaphragmatic vagotomy was done, showed the highest proportion of failures, but the later cases, though not reported in detail, were exceedingly successful. They believe that the early failures were due to incomplete vagal interruption, as judged by the results of the insulin test-meal which is believed to be a specific test for vagal denervation of the stomach. Other large series have come from America. CRILE [8] has done 77 cases, often with additional gastroenterostomy or other mechanical rectification, and describes his results as excellent. MOORE and colleagues [9] have had 1 failure and 3 unsatisfactory results in 33 cases. DRAGSTEDT,[2] who speaks from the largest experience of anyone, has done 140 cases, the first over four years ago, and he says that vagal resection has replaced all other methods of treating peptic ulcers in his clinic.

There are some side effects and dangers associated with vagal resection. Transient anorexia and gastric atony follow the operation, but continuous suction for three or four days will tide the patient over the danger of acute dilatation of the stomach. Gastric atony may be a more serious matter if it brings to light a mild pyloric stenosis for which no short-circuiting operation has been done after the vagal resection. A stomach which could cope with some narrowing of its exit before vagal denervation may afterwards be unable to empty itself. No constant or serious effect on any of the organs distal to the stomach has been found;
sometimes follows the operation but ceases
y. In some circumstances the balance

a man suffering from hypertension and peptic who had his vagi and his thoracolumbar resected; he died of a symptomless perforation duodenal ulcer fifteen days after the second op. *No other case of perforation after vagal* seems to have occurred, but it may be unwis treat the peptic ulcer of a hypertensive by resection or the hypertension of a dyspeptic by lumbar sympathectomy. WEEKS et al. also another fatality after vagal resection which is esting. The patient died on the table from arrest, symptoms of which appeared while the were being manipulated. The question arises handling of the vagi has repercussions on the and it would be interesting to know whether graphic studies of the heart during dissection of vagi have been done.

Any new technique, especially if founded elegant theoretical considerations, will evoke rary enthusiasm. But though it is too early to pass judgment, it seems that vagal resection will more than a passing fashion. If the claims made for it are substantiated it will have a perm place in the treatment of peptic ulcer. Appa vagus does not regenerate after it has been cut, and the passage of time shows the effects of resection to permanent the operation will become the answer to the majority of peptic ulcers.

Life for the Long Lived

"AFTER reading many books on old age, I Cicero the most irritating," complains Dr. R. BENNETT in a lively scholarly treatise [1] written from the vantage-point of the eighth decade of life objects specifically to the insincerity and lack of humour manifest throughout the *De Senectu*— "this tiresome work." According to Cicero, Cato gave four reasons for a miserable old age: having nothing to do; enfeeblement of body; depriv of pleasure; and the approach of death. actually, of these four reasons, only the last an inevitable result of life, whether long or short. is now well established that old people like to occupied, that many of their ills yield to treatment, that they take pleasure in simple things, and that so long as they get these things and can live under conditions of reasonable comfort they pay more attention to the thought of death than the rest of us.

With the account of the measures adopted Aberdeen for lightening the burden of age (p 106), our series of articles on the modern care of old pe comes to an end. They show what is being done, and down the country, to get rid of shoddy standards of treatment, to replace carelessness by attention to the welfare of old people, and to restore bodily function and zest for living in those who must depend to a greater or less degree, on strangers for care their later years. Our study has ranged from t receiving active treatment in hospital to those in institutions, residential homes, almshouses, corporation bungalows; and we have shown how cities—Glasgow and Aberdeen—are tackling the of the old from many directions. One vivid lesso

NURSING STANDARDS

THE General Nursing Council have been strongly riticised in these columns and elsewhere for setting tandards which exclude many suitable girls from the rofession of nursing. At a time when the hospital ervices can be saved *only by a large influx of new nurses* hey would deny the title of nurse to anyone who does not follow a syllabus which they are making more and more academic. In justification of this policy they send us this week through their registrar a letter announcing hat British Columbia no longer feels able to recognise our training schools—on the ground that the educational qualifications for entry are too low and the standards of training unequal. This shows, says the registrar, the necessity to raise rather than lower the standards of nursing education in this country; and we quite agree. What we have proposed, and still propose, is that every nursing candidate should qualify first in bedside nursing of a higher standard than is required today: this bedside course, we have suggested, might last two years. Those with the right abilities and educational background should then take a much more exacting and scientific course for State registration than has so far been offered. Qualification in bedside nursing would give a woman the title of nurse, and State registration would give her the rank of sister.

Thus the *Nursing Times* is only partially correct in saying last week that we advocate "a shortening and simplification of the training, to open the profession to larger numbers of potential nurses." Unlike the General Nursing Council, we think the profession should find room both for the woman with intellectual ability and for the woman with practical capacity. Both are urgently needed within its ranks.

PROBLEM GIRLS

THOUGH delinquent adolescent girls present more intricate problems than delinquent boys of the same age, we have more and better institutions, with more trained intelligent staff, for the care of boys than of girls. A joint committee of the British Medical Association and the Magistrates Association, who have just reported[1] on the problem of unstable adolescent girls between the ages of 13 and 17, suggest that the causes and nature of the problem are not always clearly appreciated by those dealing with such girls, and that the general attitude towards them is often mistaken, the decision of the court or other authority serving only to increase their difficulty. When a girl appears in court it is seldom as a result of her first misdemeanour; if charged with theft she has generally stolen before, if with a civil offence she usually has a history of sexual deviation and defiance of parental control. Her standards of conduct, or misconduct, are thus well established. The probation officer often finds that her environment has been poor; her home life has been broken by the death or absence of one or both parents, there has been gross overcrowding or great disharmony. Lacking love, stability, or security in the home she tries to find compensations outside. Moreover some girls are unhappy in their jobs: while others, having been brought up in an institution, are self-centred with little sense of responsibility towards others, and with no clear idea of the value of money. Yet, as the report notes, many girls in equally unpromising circumstances overcome them and do well. "The fundamental cause of the delinquency is usually found by the psychiatrist to be some defect of character structure, not always amounting to a mental defect." Some, indeed, are dull and backward, even to the point of feeble-mindedness; but moral or social deficiency is not necessarily associated with a low intelligence quotient.

The girl with an I.Q. below 60 usually has a childish appearance and manner, and is facile and friendly but incapable of loving adequately either her parents or anybody else; lazy and lacking in initiative, she is impatient of control and sexually undiscriminating. Most of the unstable girls who come before the courts, however, are brighter than this, with an I.Q. between 70 and 90; well developed physically, they resemble in their emotions the lower-grade girls just described, though they are more discriminating in the type of man they go about with and are more skilful in telling lies to cover up their misdemeanours. Though docile when under authority, they are usually only waiting to get free to return to their former style of life. A special type of girl is over-credulous and romantic, easily believing herself in love though actually incapable of deep affection, and over-sexual in her behaviour. Such girls may contract venereal disease, give birth to illegitimate children, or become true nymphomaniacs; but they are capable of responding to psychotherapy, and should be encouraged, the report suggests, to undergo voluntary residential treatment.

The girl brought into court suffers a good deal of mismanagement. She may first be put under the probation officer, and though she may intend to settle down at home, she has no sense of "obligations" as a corollary to "rights," and will very likely disappear again after the first row at home. By the time she is found she has usually had sexual relations with one man or several. This results in a stay in a remand home, where she hears the boasts of her companions and boasts in return. After a brief interview with a psychiatrist, and a medical examination, she reappears in court, and is perhaps sent for a period to a hostel. Hostels are scarce, and the one chosen is not necessarily the most suitable, but the one which has a vacancy. If this fails, and she transgresses again, the approved school remains. This is sometimes reached only after 4 or 5 months in a remand home, and a further 10–12 weeks in a classifying centre—both upsetting experiences. When the time of detention is over the girl goes back to the home in which she first broke down as a citizen.

The report points out that arrangements for dealing with these girls are not only inadequate—they are often of the wrong kind. "It is wrong to treat as guilty of an offence a girl who needs and cannot find care and protection. An emotionally unstable girl needs a special type of remand home." If we are to deal effectively with such girls, the report suggests, the nature and causes of their misbehaviour must be more fully recognised, and more skilled staff and more clinics and institutions must be provided for their investigation and treatment. A better home environment means a better chance; good housing and freedom from overcrowding, as well as better nutrition, are important for normal growth. The Ministry of Labour's schemes for vocational guidance should also help; for many girls, rebelling against drab employment, are merely seeking some interest which will bring colour into their lives. Clubs and youth organisations encourage development of the sexual instinct along accepted lines. For those who need psychiatric investigation selected approved schools should be set aside and visited regularly by psychiatrists. In hostels, approved schools, or colonies for such girls the staff should be carefully chosen and trained; needless to say, many more such institutions are needed.

Emotionally unstable girls do badly in remand homes, and should be received, for preliminary investigation, in special observation centres. Afterwards they need 2 or 3 years in a suitable school, hostel, or institution, are also promoting old people's clubs, which benefit many, giving them company and occupation, and somewhere to turn when they need advice and help; in some places a lunch club, often combined with a social club, has proved successful. Visits are paid to lonely old people in their own homes or institutions. In many areas mobile canteens are being started with the help of the British Red Cross and the Women's Voluntary Service: these take cooked meals to old people in their own homes once or twice a week. The committee's experience confirms our belief, based on the current study, that where good work is being done for the old no special conditions favouring success were present at the outset. In every case a single person or a small group of people set out to see what could be done; and in the face of frustration, opposition, and every sort of structural drawback they have achieved remarkable things. But these are the exceptions.

Obstructing a Coroner

THE inquest proceedings in the Clements case, which attracted popular attention last month, raised one point of great professional interest. The coroner referred to the post-mortem examination "performed privately by Dr. Houston as arranged by Dr. Holmes." He found it "very disturbing" that this should have occurred without his authority. Dr. Holmes, said the coroner, admitted his own uncertainty as to the cause of death. He therefore had a duty, as the medical attendant of the deceased Mrs. Clements, to report the matter forthwith to the coroner or his officers so that the machinery of the inquest could be set in motion; from that time onwards it was the coroner's responsibility. "If this case had been reported to the coroner as it might have been and ought to have been, the interests of justice would have been better served." A somewhat similar view was expressed at Wrexham lately by the East Denbighshire coroner, where there was evidence that the house-physician at a local hospital had been unable to diagnose the cause of death. "In a case where the cause of death is unknown," said the coroner, "you should, out of courtesy and before any post-mortem is performed, consult the coroner to ascertain whether he agrees." Such observations may create some doubt in hospital practice. At every hospital autopsies are performed where patients have died of natural but not definitely ascertained causes; in these cases, where there is no reason to suspect foul play, the coroner is not informed.

The coroner has, of course, a statutory duty to hold an inquest where death is due to a non-natural cause. It is for him to decide whether the case is one in which he will hold an inquest, and, although Lord Ellenborough made some vigorous remarks in R. *v.* Kent Justices (in 1809) upon the practice of holding unnecessary inquests, the coroner is justified even if the information whereon he acted proves to be untrue, provided that he honestly believed that death might be due to some non-natural cause (R. *v.* Stephenson: 1884). Needless to say, he must not be thwarted in the exercise of his jurisdiction. In R. *v.* Clerk (1702), where a body had lain buried for seven months, Chief Justice Holt remarked "the coroner is not obliged to go ex officio to take the inquest but ought to be sent for, and that while the body is fresh, and it is a misdemeanour to bury the body before, or without sending for the coroner... it is a matter indictable to bury a man that dies of a violent death, before the coroner's inquest have sat upon him." Just as it is an offence to prevent an inquest by burial, so it is an offence to dispose of a body by cremation in such manner as to prevent the coroner from holding his inquest. This was the decision of Mr. Justice Stephen in R. *v.* Price 1884) where Dr. Price, "the last of the Druids" had attempted to cremate his child on a Welsh mountain-top. Cremation, said the judge, was legal if not done in such a way as to be either a nuisance or an obstruction to the course of justice. Another case of unusual disposal of a body was the subject of a prosecution in R. *v.* Purcy in 1933.

A man and his wife and daughter, were convicted at Northampton quarter sessions of having obstructed a coroner in the execution of his duty by disposing of the daughter's infant child in such manner as to prevent an inquest being held on it. The body was found under a hedge and the death had not been registered. Post-mortem examination showed death to be due to broncho-pneumonia *accelerated by neglect*, but death was ascribed to natural causes. On appeal, the Lord Chief Justice held that *the foundation of the charge must be* that the case was one where a coroner had a duty to hold an inquest. This fact had by no means been established. Even if the fact had been proved, the court could see no evidence that the accused intended to obstruct the coroner.

To obstruct a coroner by removing organs or otherwise tampering with a body must be just as much an offence as obstruction by disposing of the body. The decision of the Court of Criminal Appeal in R. *v.* Purcy, however, suggests that a medical practitioner who conducts an autopsy in a hospital in a case where death, though not definitely explained, has been due to natural causes commits no offence. The burden would lie upon the prosecution to prove that his action was done with intent to obstruct the coroner.

It is natural and indeed proper that coroners should jealously uphold their jurisdiction. At the inquest on the Leigh Pit explosion victims in May, 1934, the coroner announced that some bodies had been interfered with and a portion of one body had been removed. It appeared that samples of blood had been taken in an examination for carbon monoxide. Addressing a witness, the coroner stated for the information of the witness and others for the future that "no body must be tampered with after death without the permission of the coroner." He gave the witness an opportunity to apologise for what had been done—"you may be doing several *things that should not be done, and one is contempt* of court." This threat was perhaps an excess of authority. As the judge of a "court of record" the coroner can commit persons for contempt of court. Since, however, his court is presumably graded (with the county courts) as an "inferior court of record," it seems that he has no power to punish for contempts not committed in the face of the court. If so, anything *done outside the court is no contempt.*

The recent inquest on Mrs. Clements disclosed that suspicions were not unfounded. In these circumstances the coroner's warning *needs no emphasis.* Be that as it may, it would be useful if some official ruling could clarify the limits within which hospital autopsies may properly take place.

viruses is such that transmission to man would indeed surprising when every known means has failed to ect other lambs. Nevertheless, as the Oxford writers ggest, an *extra factor*, such as a *copper deficiency*, ay be needed to secure transmission within the species. enewed efforts should be made to clear up this question, pecially in view of the recent claims of Margulis al.[2] in Russia to have isolated a virus in relation to sseminated sclerosis.

From the laboratory comes news[3] of a further attack n the pathogenesis of the demyelinating diseases in rms of immunity reactions. For many years attempts ave been made to produce these lesions by the injection heterologous brain-tissue, and, though the results have ometimes been equivocal, the experiments of Ferraro nd Jervis[4] left little room to doubt the validity of the ethod. But positive results entailed many months f waiting before symptoms appeared. The advance egistered in this latest work lies in the success obtained ith homologous brain-tissue, and in the speeding p of the reaction by the addition of "adjuvants" o the inoculum. These adjuvants, used by bacteriologists for the enhancement of immune reactions, include uch substances as killed tubercle bacilli, liquid araffin, and the ointment base, 'Aquaphor.' When hese were added by Kabat and his co-workers[3] to mulsions of brain-tissue the time elapsing before ymptoms developed was usually 3–5 weeks from the rst injection, and a large proportion of the monkeys eceiving inoculations of adult brain-tissue, whether omologous or heterologous (rabbit), developed cerebral esions. These predominated in the central or subortical white matter of the cerebrum, pons, optic nerve, nd central white matter of the cerebellum; the spinal ord was little affected. The lesions were related to lood-vessels and consisted, in the early stages, of periascular polymorphonuclear infiltration associated with edema, degeneration of myelin, and occasionally fresh æmorrhages. The axis-cylinders were relatively preerved. In monkeys that survived beyond the third r fourth day after the onset of symptoms there was vidence of the progressive subsidence of the inflammatory henomena, with replacement of the leucocytes by microglia. In the severity of the reaction described nd illustrated these experimental results perhaps bear closer resemblance to acute hæmorrhagic leuconcephalitis than to disseminated sclerosis as we usually now it. The illness produced in the monkeys was owever of considerable severity, and death mostly ook place within a few days of the onset. The relationhip between these forms of disease is still undetermined.

In further experiments, emulsions of either fœtal abbit brain devoid of myelin or adult monkey cerebral rey matter failed to produce the lesions. The antigen herefore appears to be bound up with the myelin— highly significant observation. But the myelinheath is a complex structure, and it is to be hoped that uture work will pursue the analysis into the realm of nown chemical compounds. In the meantime it is ifficult to synthesise the various conflicting views concerning the ætiology of the demyelinating diseases. The uccess of Kabat and his co-workers with homologous rain-tissue suggests that auto-immunisation may play part in the diseases in man. It is thus possible that ertain infections, especially viruses, may act in some ay on the brain with the result that antigens are iberated into the blood-stream. The antibodies subequently produced might then be expected to react with he original tissue: analogies are to be found in infections lsewhere in the body. Finally, if it is demonstrated hat the deficiency of some trace element, for example copper, is required for the interaction of infective agent and myelin, a coherent picture of the mechanism will be obtained. In this, however, speculation is carried far beyond the limits of present knowledge.

MIDWIFERY UNDER THE ACT

THE view is gaining ground that midwifery, in so far as it is undertaken by doctors, should be concentrated in the hands of doctors with a special interest in this work, and should no longer be undertaken by all general practitioners, regardless of whether they have acquired special skill in its practice, or are continuing to do enough midwifery to keep up their skill. The arrangements proposed by the Ministry of Health for the provision of maternity services (summarised on p. 105) will not therefore surprise anyone who has observed the recent trend of informed opinion.

Under the Act, the Minister was enabled to lay down the qualifications of doctors to be eligible for this work. The suggestion of such a limitation on the right of a qualified man to undertake all types of practice was repugnant to many doctors. Others, though recognising the need to ensure a high standard of midwifery, were reluctant to agree to a clause that might make a medical (or even a lay) officer of a health authority the Minister's agent as arbiter of the fitness of a practitioner to practise midwifery. The proposals contained in the present circular will do much to allay these fears. The screening committee, consisting of local general practitioners, a consulting obstetrician, and the local health authority's medical officer of health, should be a sufficiently liberal and informed body to compile without bias a satisfactory list of approved practitioners. It is good to see that no diploma will be needed, and it is to be hoped that the list will include the largest possible number of competent general practitioners, consistent with their being able to do enough midwifery to remain competent. It is also proper that doctors whose names are not immediately acceptable should be told why, and should be given the chance of being included later after further postgraduate training and experience. Given the safeguards that the committee is local, not central, is wholly professional, and is drawn from no single professional group, and that the approved lists will remain under continuous review, it seems unlikely that the new proposals will cause serious hardship, or any unjustifiable restriction of professional freedom.

QUEEN'S NURSES' APPEAL

AN appeal for £400,000 is being made by the Queen's Institute of District Nursing to supplement their long-service fund, which provides annuities of £40 a year on retirement for Queen's nurses who are too old to come into the nurses' superannuation scheme. These nurses worked in the days when conditions in the homes they visited were far worse than they are today, and the nurse's pay was not such as to encourage saving for old age. By their example and unobtrusive teaching in hygiene they truly earned Florence Nightingale's description, "the civilisers of the poor." Today more than half of the 8000-odd district nurses in the country wear the blue uniform and badge of the Queen's Roll. About 1000 Queen's nurses who have retired or will soon do so must rely in their retirement on the institute's annuity and the old-age pension. Under the National Health Service Acts district nursing will become the responsibility of local authorities, and it will be for them to decide how far to make use of existing voluntary bodies; but their decision will not affect the position of these nurses.

SIR ALFRED WEBB-JOHNSON has been re-elected president of the Royal College of Surgeons of England for a preferably run on colony lines. Many would benefit by a short transition period in a hostel after leaving an approved school and before returning to their own homes. The joint committee end by affirming their belief that the psychiatric approach is the right one, and will succeed in most cases.

REACTION TO NERVE INJURY

WE have still much to learn about the response of the organism as a whole to wounding. Dr. W. K. Livingston, professor of surgery in the University of Oregon, investigated this problem during the late war, partly by the detailed questioning of wounded men as to their subjective experiences during that period before arrival in hospital concerning which clinical data are so scarce. In a Moynihan lecture at the Royal College of Surgeons on July 8 he discussed his findings in 1278 cases of peripheral nerve injury treated in the U.S. Navy Medical Service.

In the first place, 70% of these patients felt no pain at the time of wounding; during convalescence only 15% suffered severely, and only a third felt any pain. The appreciation of wounding was rarely dramatic; one in four had no sense of impact at all, and accurate discrimination as to the size of the fragment and its degree of penetration was extremely rare. Careful questioning revealed that the immediate sensory and motor disturbance was nearly always much more extensive than appeared at the first examination in hospital. The initial result was a flaccid paralysis of the limb, with involuntary movements, combined with a state of mental dissociation from the part, which might fix in a vice-like grip or wriggle and twitch as if of its own volition. There was often an overpowering conviction that the limb had been completely shot away at the hip or shoulder, even though it was obvious that this was not so. About a third of these cases of peripheral nerve injury experienced sustained tonic or clonic involuntary movements. A small group of patients were subject to hallucinations of posture during the paralytic phase—vivid and convincing impressions, sometimes recurring for several days, that the affected limb was in a certain position other than its visibly true one.

The paralytic phenomena were particularly interesting. There were a few cases of transient remote reflex paralysis, involving a site proximal to the actual injury or in the opposite limb, and without organic local damage; these somewhat resembled cases reported by Weir Mitchell in the American Civil War, though in those the paralysis lasted longer. In Professor Livingston's series, 4% of the whole group experienced a total quadriplegia lasting a few seconds or minutes, and this was particularly frequent in brachial-plexus injuries where every seventh man was so affected. The victims were conscious and some could speak, but they felt as if they possessed only a head with no body below it. This feeling then passed off, leaving the residual definitive picture of the actual nerve lesion, but it was sometimes followed by postural hallucinations in which the body might be felt to take up an acutely flexed position, with legs drawn up. Characteristic features were the sudden, immediate, and complete quadriplegia, the retention of consciousness and orientation, and the rapid total recovery of function. Stimuli affecting the head were felt normally, or hyperacutely, and there was often some appreciation of the real state of the body in that the damage to the wounded limb was felt to be more "genuine" than the widespread paralysis. Motor function in the head was normal, and the intact state of the anterior horn cells was evidenced by violent flexor spasms in some patients.

The explanation of these phenomena is not clear, though Professor Livingston was convinced that it must be sought in physical and not psychological mechanisms. These transient reactions to injury may jeopardise on the battlefield, and are more likely to be the of physiological changes than of subconscious moti Paralysis is probably the result of an overpowering lation of nerve-fibres produced by the large amount energy which is liberated by a missile within the space of the limb, disrupting fascia and stretching and nerves. It may act by overstimulation and of motor fibres, or by massive and sustained sensory stimulation. The quadriplegia is rather niscent of spinal shock and cerebral concussion. barrier seems to intervene between the cerebral and the periphery, and the rapid complete recovery communication resembles the re-establishment of wireless circuit after interruption. The older of molecular disorganisation or synapse damage concussion do not seem to apply here. Rather appears to be an initial massive excitation of neur within the central nervous system, with after-discharge and subsequent decrease of excitability. Some sort of cerebral dysrhythmia and desynchronisation must occur and it is important also not to overlook the gross physical jolt to the brain and cord which must be transmitted along main nerves by such an injury as a high-vel penetrating wound of a limb plexus.

ÆTIOLOGY OF DISSEMINATED SCLEROSIS

RECENT contributions to the problem of disseminated sclerosis have been surprisingly diverse both in their approach and superficially in their implications. First may be mentioned a study "in the field" by the workers from the department of neurology in Oxford, together with J. R. M. Innes, well known for his work on sway-back in lambs. This disease, it will be recalled, is a demyelinating form of encephalopathy bearing some resemblance to Schilder's encephalitis in man. It occurs not only in this country but also in Australia, New Zealand, South Africa, parts of South America, and possibly in Sweden. Our knowledge of its ætiology is incomplete, but in spite of repeated attempts at transmission no evidence exists to show that it is infective. Its incidence seems to be closely linked with the availability of copper to the developing animal at the time when myelination is in active progress. This being established and generally accepted, it is startling to learn[1] that four of the seven principal members of the Cambridge team who worked on swayback have now developed a neurological disease which "would confidently diagnosed as disseminated sclerosis by any neurologist."

Though disseminated sclerosis is a fairly common condition, it would be strange if this odd juxtaposition of two demyelinating diseases were a pure coincidence. But interest in the matter must be tempered with more than customary caution. Disseminated sclerosis has not been proved in any of these four cases; no more definite diagnosis than "neurological disease" has been made. As to the victims, we read that the sister of one died of disseminated sclerosis, and this man had no contact with the disease in the field but was concerned with laboratory analysis of blood, tissues, soils, and pastu Another was an agricultural advisory officer concerned with field inquiries "who may have handled a moder number of living cases, but had no contact with autops work." Yet two of the three still unaffected workers were extensively engaged with the pathological side of the work and must therefore have been heavily exposed to any potential virus. If contact with living affec lambs is a means of acquiring the disease it is rema able that we have as yet learnt of no such disease amo those tending affected herds. Again, species-specific

ruses is such that transmission to man would indeed surprising when every known means has failed to ct other lambs. Nevertheless, as the Oxford writers gest, an extra factor, such as a copper deficiency, y be needed to secure transmission within the species. newed efforts should be made to clear up this question. ecially in view of the recent claims of Margulis al.[1] in Russia to have isolated a virus in relation to seminated sclerosis.

From the laboratory comes news[2] of a further attack the pathogenesis of the demyelinating diseases in ms of immunity reactions. For many years attempts e been made to produce these lesions by the injection eterologous brain-tissue, and, though the results have etimes been equivocal, the experiments of Ferraro Jervis[3] left little room to doubt the validity of the hod. But positive results entailed many months waiting before symptoms appeared. The advance rted in this latest work lies in the success obtained h homologous brain-tissue, and in the speeding of the reaction by the addition of "adjuvants" the inoculum. These adjuvants, used by bacterio-ists for the enhancement of immune reactions, include h substances as killed tubercle bacilli, liquid affin, and the ointment base 'Aquaphor.' When se were added by Kabat and his co-workers[2] to ulsions of brain-tissue the time elapsing before ptoms developed was usually 3–5 weeks from the t injection, and a large proportion of the monkeys eiving inoculations of adult brain-tissue, whether mologous or heterologous (rabbit), developed cerebral ions. These predominated in the central or sub-tical white matter of the cerebrum, pons, optic nerve, d central white matter of the cerebellum: the spinal d was little affected. The lesions were related to od-vessels and consisted, in the early stages, of peri-cular polymorphonuclear infiltration associated with lema, degeneration of myelin, and occasionally fresh emorrhages. The axis-cylinders were relatively pre-rved. In monkeys that survived beyond the third fourth day after the onset of symptoms there was dence of the progressive subsidence of the inflammatory enomena, with replacement of the leucocytes by roglia. In the severity of the reaction described d illustrated these experimental results perhaps bear closer resemblance to acute hæmorrhagic leuco-cephalitis than to disseminated sclerosis as we usually ow it. The illness produced in the monkeys was ute of considerable severity, and death mostly ok place within a few days of the onset. The relation-ip between these forms of disease is still undetermined.

In further experiments, emulsions of either fœtal bbit brain devoid of myelin or adult monkey cerebral ey matter failed to produce the lesions. The antigen erefore appears to be bound up with the myelin—highly significant observation. But the myelin-eath is a complex structure, and it is to be hoped that ture work will pursue the analysis into the realm of own chemical compounds. In the meantime it is ficult to synthesise the various conflicting views con-rning the etiology of the demyelinating diseases. The ccess of Kabat and his co-workers with homologous ain-tissue suggests that auto-immunisation may play part in the disease in man. It is thus possible that rtain infections, especially viruses, may act in some ay on the brain with the result that antigens are berated into the blood-stream. The antibodies sub-quently produced might then be expected to react with he original tissue: analogies are to be found in infections ewhere in the body. Finally, if it is demonstrated hat the deficiency of some trace element, for example copper, is required for the interaction of infective agent and myelin, a coherent picture of the mechanism will be obtained. In this, however, speculation is carried far beyond the limits of present knowledge.

MIDWIFERY UNDER THE ACT

THE view is gaining ground that midwifery, in so far as it is undertaken by doctors, should be concentrated in the hands of doctors with a special interest in this work, and should no longer be undertaken by all general practitioners, regardless of whether they have acquired special skill in its practice, or are continuing to do enough midwifery to keep up their skill. The arrangements proposed by the Ministry of Health for the provision of maternity services (summarised on p. 105) will not therefore surprise anyone who has observed the recent trend of informed opinion.

Under the Act, the Minister was enabled to lay down the qualifications of doctors to be eligible for this work. The suggestion of such a limitation on the right of a qualified man to undertake all types of practice was repugnant to many doctors. Others, though recognising the need to ensure a high standard of midwifery, were reluctant to agree to a clause that might make a medical (or even a lay) officer of a health authority the Minister's agent as arbiter of the fitness of a practitioner to practise midwifery. The proposals contained in the present circular will do much to allay these fears. The screening committee, consisting of local general practitioners, a consulting obstetrician, and the local health authority's medical officer of health, should be a sufficiently liberal and informed body to compile without bias a satisfactory list of approved practitioners. It is good to see that no diploma will be needed, and it is to be hoped that the list will include the largest possible number of competent general practitioners, consistent with their being able to do enough midwifery to remain competent. It is also proper that doctors whose names are not immediately acceptable should be told why, and should be given the chance of being included later after further postgraduate training and experience. Given the safeguards that the committee is local, not central, is wholly professional, and is drawn from no single professional group, and that the approved lists will remain under continuous review, it seems unlikely that the new proposals will cause serious hardship, or any unjustifiable restriction of professional freedom.

QUEEN'S NURSES' APPEAL

AN appeal for £400,000 is being made by the Queen's Institute of District Nursing to supplement their long-service fund, which provides annuities of £40 a year on retirement for Queen's nurses who are too old to come into the nurses' superannuation scheme. These nurses worked in the days when conditions in the homes they visited were far worse than they are today, and the nurse's pay was not such as to encourage saving for old-age. By their example and unobtrusive teaching in hygiene they truly earned Florence Nightingale's description, "the civilisers of the poor." Today more than half of the 8000-odd district nurses in the country wear the blue uniform and badge of the Queen's Roll. About 1000 Queen's nurses who have retired or will soon do so must rely in their retirement on the institute's annuity and the old-age pension. Under the National Health Service Acts district nursing will become the responsibility of local authorities, and it will be for them to decide how far to make use of existing voluntary bodies; but their decision will not affect the position of these nurses.

SIR ALFRED WEBB-JOHNSON has been re-elected president of the Royal College of Surgeons of England for a seventh year.

ROTUNDA BICENTENARY

THE INTERNATIONAL CONGRESS

LAST week the foundation in 1745 of the Rotunda Lying-in Hospital, Dublin, was celebrated by an international congress, opened by the PRESIDENT of IRELAND and attended by nearly 600 doctors. At the first session, on the History of Midwifery, Sir EARDLEY HOLLAND presided. At subsequent sessions five main topics were discussed under the chairmanship of Prof. JAMES YOUNG, Dr. GIBBON FITZGIBBON, Dr. J. F. CUNNINGHAM, Dr. BETHEL SOLOMONS, F.R.C.P.I., and Prof. A. H. DAVIDSON.

Puerperal Sepsis

Prof. J. W. BIGGER said that when the Rotunda was founded childbirth fever was not very prevalent, because each midwife had a limited clientele. To bring the patients to hospital under the care of professional midwives and man-midwives exposed them to greater risks of infection, and it was surprising that the institution did not acquire a worse reputation than it did. Today infection came not from the doctor's hands but more often from some breach in the barrier between patient and patient. The organism chiefly responsible was the group A hæmolytic streptococcus; its main reservoir was the throat, and it was spread chiefly by droplets and dust. Ideally each woman should have a separate cubicle or room; for a woman at childbirth with this organism in her throat was a danger to herself and other mothers. To those who were still carriers at parturition, penicillin should be given systemically; and it should also be given to all women entering an institution where puerperal sepsis had occurred. Further, the throat of everybody working regularly in a maternity ward should be swabbed weekly, and if *Strep. pyogenes* was found the person should be put off duty till the group was determined. In the presence of group A this exclusion should be maintained until three consecutive swabs were negative. Puerperal sepsis was likely to become rarer, but if precautions were relaxed there would always be danger so long as *Strep. pyogenes* inhabited throats.

Dr. C. J. MCSWEENEY pointed out that infection of the genital tract from the throat does not explain everything: why did so many mishandled patients escape sepsis? The resistance of the patient determined the development and degree of sepsis, and though the genital tract was the likeliest site of entry its importance had been exaggerated. In 151 of a series of 247 cases labour had been normal, and in this series trauma and manual removal of placenta were less important than conditions such as prematurity and stillbirth. He was convinced that the attendants were often unjustly blamed for sepsis. At general hospitals cases must be treated by special units housed in separate wards; but in large towns the most economical arrangement was to put the sepsis units in a fever hospital. The medical and laboratory staff of a fever hospital were trained to cope with such conditions, and (unlike obstetricians) ran no risk of carrying infection to clean cases.

Mr. WILLIAM GILLIATT, F.R.C.O.G., said that even before the introduction of sulphonamides and penicillin the virulence of hæmolytic streptococci was decreasing (compare scarlet fever), and it might increase again. *Sulphonamides were of most use if given at the first rise of temperature.*

Prof. NAGUIB MAHFOUZ Pasha (Cairo) recommended routine use of penicillin or sulphadiazine when instrumental delivery is undertaken in patients admitted after rupture of membranes, or when there is respiratory infection or skin sepsis. Perineal tears should be repaired immediately after delivery—an hour's delay may lead to infection. Remnants of placenta could nowadays be removed, if troublesome, under cover of penicillin.

Prof. W. C. W. NIXON advocated regular bacteriological "snooping" to kee [illegible] clinique up to standard. In cases of prolo [illegible] believed that a clean surgical cut—cæs [illegible] less harm than mutilating tra [illegible] aking routine swabs from bet [illegible] rean section he had seldom found any organisms, even several days after the membranes had ruptured. When surgery was indicated for puerperal sepsis he preferred extraperitoneal suprapubic lower-segment cæsarean section, which Waters had performed in 250 cases with a mortality of 0·8%. The striking absence of puerperal sepsis in China and Turkey made Professor Nixon wonder whether we were losing our immunity.

Eclampsia

Dr. NINIAN FALKINER (master of the Rotunda) said that whereas mortality from sepsis is declining, mortality from eclampsia, pre-eclampsia, and toxic albuminuria was virtually unchanged. These three conditions were manifestations of a single disease—peculiar to pregnant women—which might end in spontaneous delivery without harm or might progress to convulsions. The disease sometimes developed very rapidly and sometimes very slowly. Present treatment of eclampsia was based on the belief that labour accentuates it; that control of convulsions is beneficial, that shock is particularly dangerous, and that delivery without shock will lead to recovery unless irreversible changes have taken place in brain, liver, or kidneys. The Rotunda routine today involved the use of morphine, magnesium sulphate (up to 8 grammes in twelve hours), and intravenous glucose. If the patient was not in labour, and response was satisfactory, no obstetric interference was undertaken; but if fits were uncontrolled, or coma was extreme, cæsarean section under gas and oxygen was indicated. With a patient in labour making normal progress, normal delivery in the second stage was performed, with the utmost care. Where labour was complicated by inertia and the condition was deteriorating cæsarean section was considered; and in all cases with dystocia associated with delay and probable difficulty at delivery it was demanded. Pre-eclampsia might be an urgent indication for section. In 1941–47 93 cases had been treated with a loss of 8 mothers and 16 infants. Of the 10 women having cæsarean section 2 had died (1 moribund on admission, 1 cerebral hæmorrhage), with 1 fœtal death.

Prof. H. J. STANDER (New York) summarised suggested causes of eclampsia as follows:

A. *Causes Outside Maternal Organism*
   1. Dietary deficiency: (*a*) general, (*b*) protein, (*c*) calcium, (*d*) vitamin.
   2. Infection: (*a*) pyelitis, (*b*) septic foci to infect placenta.
   3. Meteorological influences.

B. *Causes Within Maternal Organism*
   1. Constitutional predisposition.
   2. Pressure.
   3. Endocrine imbalance: (*a*) pituitary, (*b*) adrenal cortex, (*c*) others.
   4. Chemical poisons: (*a*) guanidine, (*b*) histamine, (*c*) tyramine.

C. *Causes Within Products of Conception*
   1. Placenta: (*a*) infarct, (*b*) ischæmia, (*c*) crush syndrome, (*d*) allergy, (*e*) elements.
   2. Fœtus: (*a*) endocrine imbalance, adrenal cortex, (*b*) iso-immunisation (i) Rh factor, (ii) other factors.

In groups A and B he thought further attention should be given to dietary deficiencies, endocrine imbalance, and chemical poisons. He referred to the Smiths' discovery of a toxic euglobulin in menstrual discharge and in the blood-stream of menstruating and toxæmic women. Toxæmia late in pregnancy might prove to be due to *withdrawal of endocrine support*, owing to interference with the blood-supply of the placenta. Many theories came to involve the placenta (group C.1) and usually something outside the placenta was supposed to cause the placental changes: but it was not clear at what stage of events the placenta was implicated. Iso-immunisation could probably be ruled out. What was needed now was not more theories but more data, and he described his own observations, particularly on uric acid.

Dr. J. D. HOFBAUER (Cincinnati) emphasised the rôle of the placenta, which initiates and sustains hyperplasia of pituitary, thyroid, and adrenal cortex. He regarded eclampsia as a response by sensitised vessels to pressor substances present in normal blood. Painful stimuli of splanchnic areas led to increased output of these substances, and termination of labour could be considered a physiological lumbar sympathectomy.—Prof. M. A. VAN BASTIAANSE (Amsterdam) attached much importance to interference with placental function by compression of the intervillous spaces—e.g., in hydramnios or multiple pregnancy.

Prof. SUBODH MITRA (Calcutta), impressed by the geographical differences in eclampsia, had correlated the monthly incidence in Calcutta with heat and humidity, but the results differed somewhat from those recorded in Bombay and Madras.—Prof. E. C. CRICHTON (Cape Town) had found that in South Africa eclampsia was common in areas where the soil is poor in calcium.

Mr. G. W. THEOBALD said that the mortality from eclampsia in England and Scotland remained much the same from 1911 to 1940, despite the growth of antenatal care. From 1940 onwards, however, there had been a steep decline, which must surely be connected with changes in diet. If placental changes were responsible for pregnancy toxæmia why should it be so common in Ceylon and so rare in Siam? Did placentas differ in the two countries? Food deficiencies provided the real answer, as he had long maintained.[1] Eclampsia might be followed by recovery with birth of a living child some weeks later, or might appear some days after delivery. It was a self-limiting disease, and if the woman could be kept alive for 48 hours without serious damage she would live.

Prof. JEAN SNOECK (Brussels) recalled the decline of eclampsia in Germany and Austria in the 1914–18 war. At the Brussels Hospital women's clinic the incidence of pre-eclamptic toxæmia, which was 2·09% in 1938–40, fell to 0·70% in 1941–42, rose to 0·87% in 1943–44 when more food was obtainable on the black market, and went up to 4·01% in 1945–46 after the liberation.—Dr. B. S. TEN BERGE (Rotterdam), comparing two series of roughly 20,000 deliveries, had found a fall in the incidence of eclampsia from 1·1 per 1000 in 1929–37 to 0·7 in 1940–45. The exact relation to food, however, was not clear.—Prof. A. J. M. HOLMER (Leiden) had observed a slight decrease in the blood-pressure of pregnant women during the war, when the only cases of toxæmia he had seen were in the relatives of black-market merchants. The increase after liberation he attributed to inability to cope with unaccustomed fat and protein.

Dr. T. DIXON HUGHES (Sydney) remarked that in Australia the incidence of eclampsia in sheep rises when they get a rich diet after a drought period. He believed that antenatal care is capable of reducing the incidence of toxæmia and almost abolishing its mortality. The term "fulminating toxæmia" should be discontinued because it shelters inefficient antenatal care, and toxæmia should be made notifiable.

Dr. J. S GREEN (Melbourne) also held that antenatal care and timely admission to hospital can lower mortality: in 164 cases whose first fit was after admission the mortality was 5·5%, compared with 20% in 233 cases not admitted until they had had a fit. It was important not to do too much to the eclamptic and to nurse her skilfully.—Dr. BETHEL SOLOMONS likewise urged the necessity for good nursing care, with attention to detail.

Prof. F. C. IRVING (Harvard) said that active interference with the antepartum eclamptic during fits was likely to be disastrous. At the Boston Lying-in Hospital patients were given morphine, magnesium sulphate, and 'Veratrone.' The anticonvulsive effect of veratrone was probably due to vasodilatation and relief of cerebral œdema, and it was given at 20-minute intervals to keep the blood-pressure below 150. Some 24–72 hours after convulsions ceased, labour was induced by rupture of membranes or by a dilating bag, and was allowed to continue naturally. Cæsarean section was reserved for cases with other indications such as disproportion.—Mr. D. M. STERN had used veratrone in 46 cases (some severe) with no maternal deaths; but over a third of the babies died. Accidental administration of ten times the normal dose had not been fatal.—Mr. OSWALD LLOYD had used curare with 'Pentothal' and oxygen. All cases thus treated had recovered—both of them.—Mr. R. DE SOLDENHOFF thought well of immediate rectal instillation of bromethol in any woman showing signs of eclampsia.

Prof. DUGALD BAIRD was not much impressed by veratrone: a good obstetrician could get good results in various ways. It would be very wrong to suggest that antenatal care would not prevent deaths from eclampsia. Stillbirths had behaved like eclampsia during the war years, and a statistical attack was needed.

Dr. EVA F. DODGE (Arkansas) said that in the Deep South, where diet is defective especially in protein, there was much pregnancy toxæmia. In the six years since the introduction of egg and milk supplements antenatally at her hospital there had been no eclampsia among about 600 deliveries annually. A well-balanced diet would not hurt any pregnant woman.

Prof. GORDON KING (Hong-Kong) pointed out that war diets may mean wholemeal bread and vegetables, with more vitamins than previously. In Hong-Kong the incidence of pregnancy toxæmias rose with the incidence of beriberi, and both fell after the surrender.

Shock in Obstetrics

Prof. H. L. SHEEHAN said that shock is associated with slackening of blood-flow not only through the skin but also through the kidneys, liver, and probably the abdominal viscera. The blood returned slowly to the right heart and the ventricular output was small. A rise of diastolic pressure, with a fall in pulse pressure, might be the first indication of shock, preceding the fall in both systolic and diastolic pressures. In all cases dying after more than 3–4 hours of shock he had found subendothelial hæmorrhages corresponding in distribution to the left branch of the atrioventricular bundle: these were very rare in other conditions except eclampsia and cerebral lesions. Great distension was often seen in the stomach and proximal part of the colon, corresponding to sympathetic nervous distribution, and it was tempting to speculate on a common cause for this distension and the subendocardial hæmorrhages associated with cerebral irritation. The suprarenal cortex had nothing to do with shock, and the necrosis seen in the anterior pituitary might be an effect rather than a cause. After severe hæmorrhage there was a sharp decrease in blood volume, and vasoconstriction except in the brain. The same vasoconstriction was seen in shock, where it appeared to be a harmful response interfering with visceral and cardiac blood-flow. Was it a result of sympathetic overactivity or an attempt to restore blood volume? Observations on shock at the Glasgow Royal Maternity Hospital suggested that blood-transfusion was effective where collapse was wholly or partly due to hæmorrhage but valueless where there was none. These observations, said Professor Sheehan, "completely shake my faith in the view that uncomplicated shock is due to reduction in blood volume."

Dr. A. W. SPAIN approved the title of the discussion: so-called obstetric shock was nearly always a case of shockin' obstetrics. Its origin was seldom uncertain, and what mattered most was prophylaxis by good conscientious obstetrics. In this country obstetrics was usually conscientious; but was it good? Too many undertakings in which two lives were at stake were considered suitable for domiciliary attention. The student must above all be taught (*a*) avoidance of traumatic midwifery and (*b*) effective action against postpartum hæmorrhage—in which resuscitation should be secondary to "*turning off the tap.*" In treating shock the first step was to remove the inflicting agent. Cardiac stimulants were useless; morphine was always good in a conscious patient; and excessive heat was dangerous.

Prof. W. A. SCOTT (Toronto) felt that, excluding collapse caused by drugs, the great majority of cases of obstetric shock could be evaluated in terms of hæmorrhage.

Prof. HENRI BEDRINE and Prof. M. M. PAUCOT (Lille) outlined their management of shock, which included injection of pituitary extract through the abdominal wall into the uterine muscle when needed to promote contraction.

Mr. J. V. O'SULLIVAN said that shock, arising from many diverse causes, affects the systems of the body one after another until it is universal and eventually irreversible. He pleaded for more careful antenatal care. With impending shock the fœtal heart-rate showed disturbance before the mother's, and it should be counted as a routine. In inducing labour undue purgation should be avoided. The patient's own blood was more useful to her than anyone else's; but transfusion when necessary should be prompt, using fresh blood if possible. Could we not have fresh plasma, too, when appropriate?

---

[1] *Lancet*, 1930, i, 1115.

Sir EARDLEY HOLLAND stated that in England shock and hæmorrhage account for almost half the maternal deaths. He regarded pituitary extract as the last drug to give to women in shock, and he thought many lost their lives through zealous efforts to overcome retention of the placenta. With postpartum shock the uterus might go into spasm, but if it was left alone for a couple of hours the placenta would usually be found in the vagina.

Prof. J. P. GREENHILL (Chicago) hoped that Credé expression of the placenta would be given up entirely [applause]. Similarly, the uterus should very rarely be packed. He rather favoured injection of pituitary into the uterine muscle.

Mr. K. V. BAILEY held that "rubbing up a contraction," and the Credé manœuvre as usually practised, constitute mismanagement of the third stage. But they seemed difficult to get rid of—like Queen Victoria's statue in the Dail. Those who did these things should realise that actually they were conducting an operation (though without an incision) on important abdominal organs. He described a method, employing only the flat of the hand, which avoided squeezing of uterus and ovaries and consequent sympathetic irritation.—What was usually done, said Prof. HARVEY MATTHEWS (New York), was more of a push than a Credé. He also condemned the Trendelenburg position, as interfering with respiration, and the use of heart stimulants. The body should be kept at body temperature, and oxygen should be used early.

Mr. A. W. PURDIE asked how many obstetric units provide a service to go out and deal with postpartum hæmorrhage in the home. And whom did they send? This was not a task for the junior.

Mr. F. R. STANSFIELD reported that in women apparently dead from hæmorrhagic shock he had had some success from running plasma into two or three veins simultaneously under pressure, combined with "heparinisation."

Dr. F. PRESCOTT gave the cardiovascular criteria of shock as a pulse pressure less than 10 mm. Hg or a systolic below 80. By overheating, nurses sometimes produced a fall of 30 mm. or more. A few blankets were all that was needed to preserve blood-heat: slight chill was better than excessive warmth. 'Methedrine' was helpful unless the blood volume was lowered.

Dr. J. TUMA (Prague) had found the placenta a useful source of blood for storage. At least 100 litres could be collected from 2000 confinements.

Dame LOUISE MCILROY, summing-up, spoke of the emotional factor. In the last week a hot bath every night, with chloral gr. 10–15, helped to soften the cervix: and antenatal work should be done by senior people who could impart more confidence.

Sterility

Dr. ISIDORE C. RUBIN (New York) spoke of the hazards of hysterosalpingography. The fallopian tubes, he said, cannot always rid themselves of iodised oil, and a foreign-body granuloma might form where the lumen is constricted, substituting permanent occlusion for a permeable stricture. Even the crystalloid iodide media with which he had experimented caused pelvic pain requiring analgesics. On the other hand the only pain (at the shoulder) caused by carbon-dioxide insufflation was relieved by the supine posture, and with proper care this method need cause no accidents whatever. Of 2261 supposedly sterile women whom he had treated by insufflation 590 (26·1%) voluntarily reported pregnancy. The conditions found were:

Condition	No. of cases	No. reporting pregnancy	Pregnancy (%)
Normal patency ..	1210	316	26·1
Adherent tubes ..	538	135	25·1
Strictured tubes ..	379	[illegible]	31·1
Spasm with normal patency	[illegible]	[illegible]	13·4

Dr. M. E. DOUAY and Dr. RAOUL PALMER (Paris) reported on 121 cases of complete tubal closure treated by various operations. The results (18 uterine pregnancies with 14 living children, and 3 tubal pregnancies) made them hesitate to encourage a woman to undergo operation unless either salpingolysis or salpingostomy is likely to be feasible.

Mr. ALBERT SHARMAN in 190 consecutive cases had seen no pregnancy within six months of passing a sound. Tubal block should not be diagnosed without two negative insufflations and a negative hysterosalpingography. He strongly approved of Rubin's 'Viscerayopaque' which was completely absorbed in 40 minutes.—Professor NIXON had successfully used the lighter contrast medium 'Uriodone.'—Professor GREENHILL thought that in view of the risks to life and health, plastic operations on the tubes should not be done until they gave a 50% chance of a baby.—Dr. J. S. QUIN had also found the results of operation depressing.

Dr. PETER BISHOP attributed $^1/_4$–$^1/_3$ of failures in conception to failure of spermatogenesis. Semen contained hyaluronidase (75% derived from the sperms) which was capable of dissolving the viscous gel surrounding the cumulus cells of the ovum. Without adequate concentration of this enzyme near the ovum fertilisation would not take place, and to provide adequate concentration a sperm-count of more than 60 million was generally needed. Attempts to supply the deficiency by placing hyaluronidase tablets in the vagina had given some promising initial results, but there had also been successes among controls given inactive tablets. Sperm-counts were highly variable, and at least three specimens must be examined before reaching an opinion on a man's fecundity. Pregnancy could take place despite consistently poor counts—as low as 4 million.

Prof. J. S. L. BROWNE (Montreal), co-worker with J. S. Henry and E. H. Venning, said that for implantation of an ovum the luteal phase of the cycle must last some 10–12 days. Pregnanediol appeared in the urine during this phase, whose length could thus be measured. It might be less than 10 days in apparently normal cycles or might be absent in (presumably) anovular cycles. Findings in a single cycle, however, proved little: the length of the phase was far from constant, and some women might be fertile for only one or two days in the year—which explained why pregnancy might be long delayed. Endometrial biopsy was unlikely to expose a short luteal phase. Prolongation—e.g., by chorionic gonadotrophic substances—might be possible.

Prof. HILDA LLOYD said that in some women at the mid-cycle there is deficiency, absence, or abnormality of cervical mucus; the cervical os might be plugged with a thick opaque secretion. The "cervical barrier" to conception might be overcome by stilbœstrol, which stimulated secretion of mucus, or by sulphamezathine or penicillin given systemically to counteract infection.

Dr. PALMER had got much help from examining the adnexa with a peritoneoscope inserted through the abdominal wall.

Mr. CHARLES READ discussed the relative incidence of the causes of sterility, including tuberculosis, and referred to Stallworthy's observations on spastic constriction of the fallopian tubes and its alleviation with nitrites, &c.—In India, where some 15% of marriages are sterile, and women feel their disability keenly, Prof. J. CHAKRAVERTI (Calcutta) had often seen benefit from repeated short holidays in the hills or at the sea. Endocrine treatment was, he thought, overdone, to the neglect of factors such as diet, infections, hypometabolism, and emotional stress.

Prof. A. J. M. HOLMER (Leiden) said that in Holland during the hunger blockade from September, 1944, menstruation ceased in some 80% of women, and those dying of starvation showed only a few atretic follicles. Surprisingly, most women menstruated again a couple of months after the liberation. In men the sperm-counts, which had often fallen to 1–5 million, returned to normal in six weeks.

Mr. V. B. GREEN-ARMYTAGE declared that if the State does not provide enough proteins the birth-rate will go down. Much misery would be avoided if sterile girls were detected before marriage. He denounced family-planning clinics, endometrial biopsy, the Huhner test, the vitamin-E racket," and artificial insemination. he commonest cause of cervical abnormalities was rvical erosions, often induced by chemicals and mpons. Nine-tenths of trichomonas infections were ue to tampons: yet women doctors did nothing about . In sterility the good results attributed to endocrines ere more probably due to relaxation induced by onfidence in treatment.—Dr. C. CHAPMAN (Sydney) emarked that the decadence of Western Europe was en also in the Antipodes, despite more proteins. He oped for improved results from "relaxation" induced y endocrinological investigation and treatment.

Dr. R. G. CROSS said that in Ireland the gynæcologist as expected to tackle all three factors in sterility—the oman, the man, and the marriage. There was great norance about elementary sex physiology, about the isks of trauma and other damage to sex organs, and specially about tuberculosis.—Miss M. MOORE WHITE poke of the multiplicity of factors in each case. In the uture we must find means to *prevent* oligospermia and yperplasia.

Fœtal and Neonatal Mortality

Prof. A. H. DAVIDSON regarded this as the most mportant subject of the week. Neonatal mortality in Dublin was still 5%, as it had been 200 years ago.

Prof. EBBE BRANDSTRUP (Copenhagen) said that nduction of labour, already considerably used in 1795, was originally introduced in the interest of the child. His own "medico-hormonal" method employing castor il, oxytocin, and quinine sulphate, had been effective n 65% of 407 cases. When it failed, he ruptured the nembranes: in 55% of 134 cases where the os was losed rupture succeeded. Induction carried risks large enough to increase fœtal mortality if it was misused: the size of the fœtus might be overestimated, with resultant premature birth, and the incidence of forceps delivery was higher. But in selected cases it lowered fœtal mortality. For severely contracted pelvis cæsarean section was *preferable*.

Professor GREENHILL described the first fifteen minutes of life as the most critical. In New York and Chicago hospitals the main causes of neonatal death were anoxia, primary prematurity, congenital malformations, and birth trauma. For prematurity the only preventable causes were those associated with toxæmia: during delivery analgesics and anæsthetics should be used as little as possible. Nursing was the main factor in survival, and every large town in the U.S.A. had at least one hospital with facilities for dealing with premature infants. Birth injury was usually due to bad treatment or carelessness. Asphyxia of the fœtus in utero must be prevented, and he pleaded for greater use of local infiltration instead of anæsthesia. Oxygen to the mother often helped. Professor Greenhill disapproved of early induction of labour for contraction.

Prof. F. J. BROWNE (whose paper was read by Miss G. H. Dodds) thought that induction for contracted pelvis has been misused in England—being often employed in the wrong cases and before the 37th week. As regards toxæmia he protested against the prevailing view that labour must be induced to save the mother from cardiovascular injury: the critical blood-pressure level was 160 mm. Hg. Rest in bed was the best means of bringing the pressure down. Cæsarean section was not an infallible solution of all difficulties: the child gained something by vaginal delivery, which caused a gradual increase in asphyxia—an excellent stimulus to respiration. At University College Hospital during the war premature infants were treated in the basement, with a mortality of 8·1%. This low figure he attributed to a high standard of nursing with a minimum of handling —because of the nursing shortage.

Prof. DUGALD BAIRD'S main contention was that infant mortality is an index of living and social conditions. In the lowest social group (V) the stillbirth-rate started rising at the age of 20, whereas in the highest (I) it did not rise till 30 (1939, England and Wales). In class I the stillbirth-rate in second pregnancies did not start rising till the age of 35–39, and it was three times greater in class V. He compared the national stillbirth-rates with those in a series of cases treat by specialists:

—	Classes I and II		Classes III–V	
	1st preg.	2nd preg.	1st preg.	2nd pre
Specialist ..	17	8·6	37	20·3
National ..	37	20·3	39·7	24·9

Why did the national and specialists' figures differ classes I and II but not in classes III–V? In hospit practice half the stillbirths were due to prematurit The war had seen a dramatic fall in the stillbirth-rate every age-group and every parity: in Scotland it ha fallen from 42 per 1000 in 1939 to 32 in 1944. The ide conditions for motherhood were that the mother shou be well nourished from the earliest age, that she shou marry early, that she should have a reasonable number children (4–5), and that she should be well looked aft during pregnancy. Minor differences in obstetric tec nique were of little importance compared with th mother's nutrition.

Prof. JAMES YOUNG pointed out that maternity an child-welfare work had had little effect on matern mortality (which did not fall appreciably till the intro duction of sulphonamides), or on infant mortalit (which was beginning to fall anyhow), or on the stil birth-rate (which did not fall appreciably until the war —Mr. THEOBALD thought that dietetic inadequaci underlie contracted pelvis, pregnancy toxæmia, and th "unknown causes" of fœtal death.

Dr. R. M. CORBET said that "the closer you keep th baby to the mother the better." In the Coombe Hospita where babies are left in the mother's bed, there had bee only one case of overlying in 19 years, and that in a illegitimate child. Separate nurseries for babies led t epidemics.

Dr. TEN BERGE had used german-measles convalescen serum to protect pregnant women exposed to germa measles. He suggested that every mother might hav prophylactic gamma-globulin in the first two months o pregnancy.

Dame LOUISE MCILROY did not approve of bathin babies in the first six days: it lowered their temperature She used olive oil instead.

MIDWIFERY UNDER THE ACT

THE GENERAL PRACTITIONER'S POSITION

THE Minister of Health has just issued a guide[1] to local health authorities on the formulation of proposal for carrying out their duties under part III of the Nationa Health Service Act. His circular is mostly concerned with the way in which each authority should present its schemes, and the greater part of the explanatory para graphs is merely an amplification of duties already foreshadowed in the Act. The paragraphs dealing with the care of mothers and young children, however, give for the first time a detailed and explicit picture of the future maternity services, and of the parts to be played in them by the general practitioner and the present maternity and child-welfare officers of local authorities. The following are quotations:

"In the new circumstances, as *every woman will be* entitled to a family doctor, it is probable that when she thinks she is pregnant she will consult her family doctor. Subject to *Regulations which have yet to be made*, it is contemplated that every general practitioner will be *given an opportunity* to say whether or not he desires to practise midwifery under the *general medical services* of part IV of the Act, and to answer calls by *midwives* for medical aid. . . . The experience of the practitioners who desire to do so will be reviewed by a local ad-hoc committee of a wholly professional *character* (consisting of local general practitioners, a consultant obstetrician, and the Local Health Authority's medical officer of health) in each Local Health Authority's area. This local committee will draw up a list of approved local practitioners, and will be entitled to indicate to those who are not accepted for such a list the need for further obstetrical experience. The list would, of course, need to be reviewed from time to time with such objects as ensuring that the doctors on it are continuing to undertake enough midwifery to remain competent in practice, and adding the names of future entrants to the profession as they acquire the necessary experience. The duty of a family doctor, when consulted by a woman who is pregnant, will be to see that she knows how to obtain the services of a midwife and, if he himself is not on the local approved list, to help the woman to choose a 'general practitioner obstetrician' from the approved list who will give her the necessary antenatal and postnatal care and will be present, if he thinks it necessary, or is called in by the midwife, at the confinement. An inclusive fee for general practitioner obstetricians, which will be additional to that payable for other general medical services under part IV of the Act, will be centrally negotiated with the profession."

---

[1] Circular 118'47. Health Services to be Provided by Local Health Authorities under Part III of the Act. Pp. 24. H.M. Stationery Office. 6d.

"Today a medical officer for maternity and child welfare commonly conducts both antenatal and child welfare clinics. A greater degree of specialisation—in either maternity or child welfare—should be encouraged. For this purpose, practical and continuing experience in the clinical field will be recognised as essential. It is suggested, therefore, that arrangements should be made whereby those of the Local Health Authority's medical officers (including those to be transferred to them under section 68 of the Act) who, by experience and choice, are best fitted to work in antenatal and postnatal clinics should gradually be assigned to that work, attached to the obstetrical team, and thus spend part of their time in midwifery work and in acquiring the necessary experience to enable them to enter full obstetrical practice, either as specialist obstetricians or as general practitioner obstetricians. Similarly, those of the Local Health Authority's medical officers—present and future—who are more interested and experienced in child welfare work should gradually be allocated to the Authority's child welfare centres, and spend part of their time participating in the work of an appropriate pædiatric department or children's hospital."

HOSPITAL SAVING ASSOCIATION

The future of contributory schemes was discussed at gatherings held on July 10 and 11 in celebration of the silver jubilee of this association. It was felt that a body of more than two million contributors, with an income of more than £1$^1/_2$ million, cannot just disappear overnight when the National Health Service Act comes into operation: the only problem was to determine its relationship with the State under the changed conditions. At a discussion following a celebrative dinner Lord Moran, P.R.C.P., summed up by saying that the occasion marked the betrothal of the association and the State. The other speakers, who included Sir Hugh Lett, Mr. Fred Messer, M.P., Sir Wilson Jameson, Mr. Ivor Back, and Mr. F. J. Angel, agreed that the H.S.A. must have some place in the future organisation. When the Duchess of Gloucester presented scholarships to nurses next evening 2000 group secretaries showed equal unanimity in desiring to continue their voluntary work. Sir Hartley Shawcross, the Attorney-General, assured them that the Government were anxious to retain individual voluntary interest in the work of the hospitals. Mr. Henry Lesser, chairman of the executive, outlined its ideas as to the future benefits to be received by the contributors, though he emphasised that the aim of the association would still be to help the hospitals. In this connexion Dr. Charles Hill suggested that some of the funds should be devoted to health education.

FAMILY-PLANNING CLINICS.—A list of voluntary and municipal family-planning clinics is published by the Family Planning Association (69, Eccleston Square, London, S.W.1) for the convenience of doctors, social workers, almoners, and others. Advice on subfertility is given at most clinics, and at all but 6 of the 62 voluntary clinics listed every patient is seen by a doctor.

Modern Care of Old People

VIII

INTEGRATED SERVICES AT ABERDEEN

SOME ninety years ago there was founded in Aberdeen a small hospital which had for its object "To provide moderate comfort and attendance for persons belonging to the Town and County of Aberdeen labouring under an incurable disease, and incapable of earning a livelihood, with a view to preventing the necessity of such persons becoming a burden to their friends or being obliged to draw or receive parochial relief." Only 10 beds were provided, and owing to shortage of funds only 6 patients were admitted when the hospital opened on Dec. 1, 1858. Until comparatively recently it was generally known by the foreboding name of the Incurable Hospital but it is now known as Morningfield Hospital, from the original name of the site on which the modern hospital is built.

Year by year the demands on the hospital grew, and by 1881 the number of patients had increased to 31. In 1882, owing to the developments in town planning, it was resolved to acquire a new site and to erect a modern hospital.

A good and spacious site with delightful views was selected on rising ground to the west of the city, in what was then the suburbs but within easy reach of the city. The new hospital was opened in 1884 with accommodation for some 55 patients. Since that time it has been extended, but even the 104 beds it now holds are still quite insufficient to meet the applications for admission. The waiting-list is long and the period of waiting anything from six to twelve months.

The hospital now has 72 female and 32 male patients; about three-fifths of them are more or less bedridden, and even the remainder can get about very little.

The nursing staff consists of a matron, an assistant matron, 26 probationer nurses, and 2 male nurses. In the last few years the type of case admitted has been increasingly helpless, requiring more nursing attention. Diseases of the cardiovascular and nervous systems bulk most largely, accounting for about half the admissions.

The medical staff consists of 2 visiting physicians; of recent years these have been 2 of the physicians to the Royal Infirmary, Aberdeen, so there is a very close link between the two institutions, and the transfer of patients from one to the other is relatively easy. Any acute surgical case or any case requiring specialised investigation or treatment is transferred to the general hospital. The orthopædic unit of the general hospital is at hand for the care of fractures and other bony injuries, and the advice and help of any members of the honorary staff of the Royal Infirmary is always generously given to Morningfield Hospital.

A certain amount of teaching in the wards is given to senior medical students, with advantage both to students and patients—the patients look forward to and welcome the visits of the students and many of them are a little flattered to have their cases demonstrated.

OCCUPATIONS AND AMENITIES

There is no visiting occupational-therapist, but the patients, especially the women, are encouraged to sew, knit, and crochet, and it is surprising how much work can be undertaken by what is apparently a helpless rheumatoid arthritic. One old lady, well into her eighties, throughout the war completed 80 pairs of socks per annum as her bit towards victory.

The wards are of varying sizes, the largest containing 12 beds. There are two single-bed wards, several wards for 2 patients, and several for 4 patients. On the whole, the four-bedded ward seems to be the ideal: it is small nough to be homely, and allows for the grouping of ongenial patients together. In the hospital grounds here are sun parlours in which, even in winter time, he up-patients spend a large part of their day.

Religious services are held every Sunday throughout he year and the secular side is not forgotten, for a large umber of concerts are given by various societies; these re looked forward to and much enjoyed by the patients.

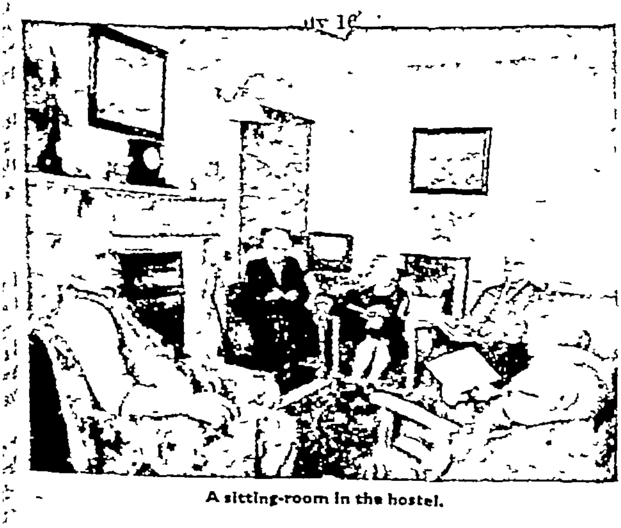
THE NEED FOR BEDS

When building is again possible, it is hoped to make room for an additional 40 to 50 beds, bringing the total up to 150. This seems to be about the optimum number for a hospital of this nature—small enough to avoid the danger of institutionalism, but allowing for close and effective coöperation with the key hospital of the area.

Before the late war accommodation for the chronic sick and elderly infirm of Aberdeen was provided by the local authority and one or two voluntary bodies. In the local-authority hospitals there were about 150 beds for the chronic sick; the Roman Catholic community had beds for 40–50 patients; and in 1937 the Church of Scotland founded an Eventide Home, taking about 40, in a converted country mansion seven miles from the city. All told, there were probably some 300 beds available, but these were quite insufficient to cope with the demand for places. In the recent hospital survey of the North-east Region the surveyors suggested as a possible figure 1·5 beds per 1000 for the chronic sick; but in the city of Aberdeen alone, with its population of 165,000, this would mean only about 250 beds, a number which under present conditions of housing would certainly be inadequate. An accurate figure could be decided on only by undertaking a thorough social survey, but a guess might put the figure at between 2 and 2·5 beds per 1000.

HOSTEL, HOME VISITS, AND AN OLD-AGE CLUB

In 1945 an Old People's Welfare Council was founded, one of its main objects being to provide a hostel or hostels for the elderly infirm, who, though unable to run a house of their own, required domestic care rather than hospital treatment. Two adjacent houses were acquired with a large and attractive garden in common. These houses, after alterations, will accommodate 30–36 residents. One of the hostels—St. Aubin's—is already active, and already some valuable experience has been gained. As in the Hill Homes, the 12 residents, who are almost all old pensioners, collect their pensions and supplementary pensions and pay the hostel 33s. per week. There are as few rules and regulations as possible. The residents are free to come and go as they please and to have their friends to visit them. The houses are within the city, on a convenient bus route, so access to the central parts is only a matter of a few minutes' ride.



A sitting-room in the hostel.

St. Aubin's Hostel.

That hostels of this description are badly needed is clear from the large number of applications made, far in excess of the accommodation available. Hitherto applications have been restricted mostly to the old pensioner class, but there is an equal if not greater need for similar accommodation for the "new poor"—the class of person who can afford perhaps 2½ to 3½ guineas a week, but whose need in a world of rapidly rising cost of living is becoming desperate.

The council has a ladies committee of 62 voluntary workers, each of whom undertakes to visit a couple of old folks living in their own homes once or twice a month. About 270 old people are thus visited, and the visits are much appreciated. The ladies committee carefully assess the needs of the old people and put them in touch with the appropriate bodies of people to help them—to treat vermin infestation, or arrange medical aid, rent relief, supplementary pensions, or domestic help, or to help them to get bedding, second-hand clothing, or whatever else they need. The council also run a library, of which the old folk take full advantage. "Meals on wheels" are under consideration and the need for such a mobile meals service is being studied.

Another aspect of the council's work is the development of an Old-age Club, open to non-residents. Fortunately within the garden of the hostels there is a very large garage which can be readily adapted to such a purpose and the council plan to complete this by the end of the year.

By the creation of such a club in association with the hostels it is hoped to build up what would in effect become an old-age welfare centre to which any old person would be encouraged to come for advice and help.

Some such coordinating centre will be welcome even when the new Health Service Act becomes fully operative. In the recent report of the British Medical Association committee on the care and treatment of the elderly and infirm the establishment of geriatric units in the key hospitals is strongly recommended. In the future such units would form the natural coordinating centre, but it may be many years before they are functioning. Meanwhile the creation of such centres could usefully be undertaken by voluntary bodies such as the old people's welfare councils which are being set up throughout the country.

In England Now

A Running Commentary by Peripatetic Correspondents

DOCTORS in Canada work, like their American colleagues, in offices, not in consulting-rooms or surgeries. Like us, they are gregarious. In consequence, complete office blocks are turned over to the medical fraternity. In Toronto, the Medical Arts Building is of skyscraper proportions—a sort of Harley Street turned up on end with over 1000 denizens. This has great advantages when second opinions are required. The switchboard and message-taking department, where each doctor's appointments book is kept, is a marvel of efficiency. Strangely enough, in all this place there are only three psychiatrists. Whether this is a tribute to the sanity or a sign of the conservatism of the Canadians I do not know. Canada is, as far as I know, the only country in the world to have had a psychiatrist as deputy minister of health. This post is not quite what it sounds, for the deputy minister, in the Dominion and provincial governments, is not a politician but a civil servant. This particular deputy minister was a very brave man, for he advocated the abolition of Father Christmas. The results were not such as to encourage Sir Wilson Jameson to follow suit.

The level of general practice in Canada is very high. A Canadian G.P. is ashamed if he cannot stabilise his own diabetics; and he has to be an all-rounder, because the distances are terrific. Canada is bigger than the United States—over 60 England and Wales's could be fitted into it—yet in this vast space there are under 12 million people. Add to this a winter below zero Fahrenheit most of the time, in parts 30° below, and you can form some picture of the life in general practice. It is nothing for a practice to extend 50 miles in each direction from the doctor's home. Saskatchewan has introduced two air ambulances which are fitted with skis in winter, and the only answer to the problem of the Canadian G.P.'s transport seems to be the owner-driven helicopter.

If the general level of Canadian medicine is high, I had the impression, confirmed by many Canadians, that at the top we could still give them points. Their hospitals, however, whether municipal or charitable (usually Catholic, and by no means confined to French Canada), are excellent. The bed : population ratio is far higher than in England, and indeed up to 90% of deliveries in some provinces take place in hospital. All patients in hospital, except those in receipt of public assistance, pay fees both to the hospital and to the doctor or surgeon. Thus, there is little free surgery, but fees are far lower, ranging from £5 to £25. A visit from a doctor may cost 10s., but the patient expects much more for it than in Britain. Often the patient calls in the specialist directly; and he has no hesitation in changing his doctor if he is dissatisfied; in consequence, sale and purchase of practices is unknown, and I found great difficulty in explaining to Canadian doctors what it was that their British counterparts in fact sold.

Very few Canadian women become doctors, but they make excellent wives and mothers. Canadian family life is as happy and stable as its great neighbour's is unstable. And the children, in this land of opportunity, have the kind of time that other children only dream about.

* * *

Last week many hundreds of us bore witness to the fame of the Rotunda. For two centuries (remarked Eire's minister of health) rolling stones from all over the world have been going to Dublin to gather a little bit of Mosse. Yet in spite of their preoccupation with obstetrics members of the international bicentenary congress must all have found their attention wandering to the city itself—"headquarters," as Dr. Ryan put it, "of the Irish Commonwealth of Nations." The transmutation of the old régime was fascinatingly illustrated by a reception at which the President of Ireland and Mrs. O'Kelly made every visitor feel welcome at the former Viceregal Lodge. Here the rooms are doubtless much as they were in the days of the viceroys, but the pictures on the walls are strong reminders of the troubles from which Eire has emerged into unexpected stability and hope. This stability, and a measure of aloofness from British worries, offers an opportunity for cultivating civilisation on the smaller scale which it seems to prefer; and in Dublin even the poorest have something of the gentility that comes of ancient riches. I now know better why one of our loveliest roses is named Irish Elegance.

* * *

Before the war the hospitals were rarely, if ever, represented at Henley, though a few boats went to other up-river regattas and some did astonishingly well in the Thames head-of-the-river races; and there were, of course, some keen crews in the inter-hospitals' race itself. Many medical students have rowed for their colleges while at the university, but on starting their clinical work they are apt to get bitten by conscience and give up rowing; and some of the others join one of the great Tideway clubs. It has been encouraging this year to find two medical crews—London Hospital and United Hospitals—entering for the Thames Cup at Henley. One could have wished for more support from one's colleagues in the enclosures, but that will no doubt come as the clubs become better known in the rowing world.

Both crews did well to win their first heats, and on Friday they represented England against the American schools. United Hospitals met Kent School, the eventual winners of the Thames Cup, and London Hospital met Tabor Academy, the runners-up. In both races the Americans won decisively, but the United Hospitals crew gave Kent a harder race than anyone else and were probably one of the fastest English crews in for that event. For a first appearance at the regatta this was an achievement.

Apart from these two eights the profession was present in force. At least two coaches and one competitor were doctors, and many medical students were rowing for other clubs, some in "Grand" crews. Of the finalists at least two winning and two losing crews contained medical students.

On the whole, the prognosis for hospital rowing is good; the infant is lusty and is likely to thrive. Given whole-hearted support, who knows?—we may yet see a United Hospitals' crew win the Grand. It's a far cry from the days in 1885 when the challenge cup for inter-hospital fours was first rowed for on the Putney to Hammersmith course.

This is only a preliminary communication because my mother stopped further experiments saying it might stop the hens laying. Nevertheless I can say that it really works—this witchcraft business of immobilising hens with their beaks on a chalk line, I mean.

Experiment 1.—I placed a hen with its beak on a chalk line (jolly difficult, I can tell you) and on letting go gradually the hen stayed there—nose to the line (looking a most frightful ass) until after half a minute she gradually raised her head about two inches off the ground, then the spell snapped and she was off with a squawk. I repeated this several times with consistent success.

Experiment 2.—I repeated experiment 1 but without a chalk line. No success at all. The hen was abusive and violent and escaped rap[illegible]

Experiment 3.—I us[illegible] white tape pinned on the lawn. Hens might like the smell of chalk because of calcium deficiency or something, but it can't be that because white tape works, if anything better.

One odd thing I noticed. There were naturally a few white feathers blowing about the lawn by then, and if one of these came within the hen's visual field she immediately raised her head to glance at it and was off in a flash. I wanted to repeat all this with different coloured tapes and trying them coronal in direction as well as sagittal, but I shall have to wait for a grant from the M.R.C.

* * *

Hitch-hiking down the Great North Road, my first lift was from a nature-cure practitioner. He spoke very kindly of doctors. Most of them, he said, did their best. Indeed, he had been at St. Ethelred's himself, but gave up orthodox medicine because he felt he needed more freedom and the right to advertise—only ethical advertising, of course. I asked what was the essential difference between his sort of treatment and ours. "Oh," he said, with a modest wave of the hand, "it's quite simple; we just go to the root of the trouble and remove it!"

This is only a preliminary communication because my mother stopped further experiments saying it might stop the hens laying. Nevertheless I can say that it really works—this witchcraft business of immobilising hens with their beaks on a chalk line, I mean.

Experiment 1.—I placed a hen with its beak on a chalk line (jolly difficult, I can tell you) and on letting go gradually the hen stayed there—nose to the line (looking a most frightful ass) until after half a minute she gradually raised her head about two inches off the ground, then the spell snapped and she was off with a squawk. I repeated this several times with consistent success.

Experiment 2.—I repeated experiment 1 but without a chalk line. No success at all. The hen was abusive and violent and escaped rapidly.

Experiment 3.—I used white tape pinned on the lawn. Hens might like the smell of chalk because of calcium deficiency or something, but it can't be that because white tape works, if anything better.

One odd thing I noticed. There were naturally a few white feathers blowing about the lawn by then, and if one of these came within the hen's visual field she immediately raised her head to glance at it and was off in a flash. I wanted to repeat all this with different coloured tapes and trying them coronal in direction as well as sagittal, but I shall have to wait for a grant from the M.R.C.

* * *

Hitch-hiking down the Great North Road, my first lift was from a nature-cure practitioner. He spoke very kindly of doctors. Most of them, he said, did their best. Indeed, he had been at St. Ethelred's himself, but gave up orthodox medicine because he felt he needed more freedom and the right to advertise—only ethical advertising, of course. I asked what was the essential difference between his sort of treatment and ours. "Oh," he said, with a modest wave of the hand, "it's quite simple; we just go to the root of the trouble and remove it!"

it only to patients whose hip-joints or knees had been jected :

The questionnaire only applies to your joint or joints.

Patient's name____________________April, 1947.

(1) *Had you, when the injections started, any :*

) *Pain ?* Standing : Yes Walking : Yes At rest : Yes
No No No

) *Stiffness ?* Yes
No

This questionnaire was sent to 90 patients, and 87 eplies were received, 62 of which referred to hips only, 6 to knees, 8 to both hips and knees, and 1 to knees and wrist, as follows :

HIPS

Total cases 70 : hips only 62 ; hips and knees 8.

Symptom when treatment began		*Improved*	*Doubtful*	*No improvement*	*Worse*
(1) Pain ; standing, walking, and at rest	55	46	4	4	1
(2) Pain ; standing, walking	8	5	1	2	0
(3) Pain ; standing, at rest	1	1	0	0	0
(4) Pain ; walking, at rest	2	2	0	0	0
(5) Pain ; standing only	0	0	0	0	0
(6) Pain ; walking only	3	1	0	2	0
(7) Pain ; at rest only	1	1	0	0	0
Total results :					
Pain	70	56	5	8	1
Stiffness	66	37	3*	24†	2
Walking difficulty	69	47	3	17	2

* One case improved for short time then failed to improve further.
† One case had 2 injections only.

KNEES

Total cases 25 : knees only 16 ; hips and knees 8 ; wrist and knees 1.

Symptom when treatment began		*Improved*	*Doubtful*	*No Improvement*	*Worse*
(1) Pain ; standing, walking, and at rest	16	11	0	5	0
(2) Pain ; standing, walking	7	3	0	3	1
(3) Pain ; standing, at rest	0	0	0	0	0
(4) Pain ; walking, at rest	0	0	0	0	0
(5) Pain ; standing only	0	0	0	0	0
(6) Pain ; walking only	1	1	0	0	0
(7) Pain ; at rest only	0	0	0	0	0
No pain in above category	1				
Total results :					
Pain	24	15	0	8	1
Stiffness	25	17	0	7*	1
Walking difficulty	23	15	0	7	1

* One case improved for short time and then failed to maintain improvement.

It is perhaps permissible, even after only two years' experience at the Royal Free Hospital clinic and a year's intensive experience at the British Legion inpatient unit at Arlesey, to make the following provisional remarks :

(1) The method, particularly as regards the hip-joint, appears to give better and more lasting results in suitably selected cases than previous methods, including injections and X-ray therapy.

(2) Its field of use is strictly limited, being greatest in early osteo-arthritis of hips and of little or no value where the erythrocyte-sedimentation rate (E.S.R.) is high and other signs of active arthritis are present. The only patient reporting as being worse after injection was found subsequently to have a greatly raised E.S.R.

(3) The value of the method can be greatly enhanced by suitable rest, extension, regular employment of suspension therapy, exercises, and the early use of callipers that free the hip or knee-joint from weight-bearing.

(4) From the variety of reactions encountered we consider that a valuable field of biochemical investigation has been opened up by this new technique, and that it is one likely to provide a number of answers to questions rheumatologists have long been asking themselves about the chemistry of joints during the progress of atrophic arthritis and osteo-arthritis.

London, W.1.

C. B. HEALD
A. J. MARTIN.

THE STUDENT AND THE ALMONER

SIR,—Since writing the letter published by you on June 21 I have seen an article by Prof. R. C. Browne in the *British Medical Journal* of June 14, in which he describes in full a scheme such as I had in mind. Surely some such plan might, with modification and perhaps some simplification, be applied not only to industrial health but to the health of any hospital patient. It is not every hospital which could organise such a service, but it should not be beyond the competence of any teaching hospital.

Dr. Eastwood (July 5) states that hospital almoners are already overworked ; this will not be the case when the new health service comes into force. Much of their time which is now occupied in a search for funds will then be released for more constructive work. High on the list of such work I would put the teaching of social medicine to students, in close coöperation with the medical and surgical staffs and outside doctors.

General practice does not lend itself to teaching. Many patients would object to a student accompanying a doctor when he visits them in their own homes, and a crowded surgery offers no scope for the discussion of cases. The student might as easily arrive for his month with the general practitioner when he was submerged by an epidemic as when he was thankfully relaxed in an unaccountable lull. Neither would be profitable for the student.

London, S.W.10. BERYL HARDING.

APPEARANCE OF PROTRUDED DISKS

SIR,—With reference to Mr. Charnley's criticism (June 28) of the illustrations in the article by Mr. Burns and Mr. Young (May 10), I have examined some sections of spine removed at routine necropsies by Dr. D. M. Pryce, and I can assure Mr. Charnley that the findings described by Burns and Young do occur, though I have not sufficient experience of numbers to say whether or not they are the most common type. It seems to be not unusual for the nucleus to herniate between the vertebral body and the annulus ; this is a little surprising if one accepts the orthodox view of the anatomical relations between these parts.

London, W.1. V. H. ELLIS.

SIR,—Mr. Creer's letter of July 12 will interest many radiologists who according to him do not agree on the value of a straightforward radiogram in the diagnosis of disk protrusions. Disk protrusions can be diagnosed from a straightforward radiogram[1] in approximately 50% of all the cases, and figures which are now being in Parliament. Since June 2 there has been, except in central London districts, no delivery of letters after midday until the next morning. A letter takes longer to reach London from some parts of England than does a letter from the Antipodes.

House of Commons. E. GRAHAM-LITTLE.

TECHNIQUE OF LARYNGEAL ANÆSTHESIA

SIR,—Prof. R. R. Macintosh's useful contribution (July 12) fails to stress the disasters which may result from the abolition of the cough reflex in the post-anæsthetic recovery period, where laryngo-pharyngeal anæsthesia has been deliberately produced by the indiscriminate use of a local anæsthetic such as cocaine hydrochloride, &c., in any strength or quantity. He obviously has this in mind when he writes, "I use a weaker solution of cocaine than that generally advocated. Analgesia from a 3–4% solution is slightly slower in onset and shorter in duration. . . ." These lines should be printed in large capitals.

The hazard of a nasal operation (which depends on ischæmia secured by the local application of cocaine hydrochloride, &c.) is the unnecessary and unwitting laryngo-pharyngeal anæsthesia produced either by the surgeon's nasal spray, by nasal packs, or by the deliberate direct application of local anæsthetic to the laryngo-pharynx. This will abolish the cough reflex, the watch-dog of the trachea; and if the reflex is still absent at the end of the operation, blood, even if the amount is small, will trickle insidiously into the trachea from the postnasal space. A gradual and fatal asphyxia will thus be produced in the early postoperative period, after the surgeon and the anæsthetist have departed and the patient has returned to the ward. The patient is there left in the charge of a nurse who is unable to recognise the gravity of the condition until too late. Should this concealed intratracheal hæmorrhage be recognised in time, immediate aspiration through a bronchoscope will yet save the patient; I was fortunate to be able to do this in a colleague's case many years ago. The amount of blood in the bronchi, viewed at necropsy, may be so small that it would be difficult to assign the fatality to it, were one not familiar with the sequence of events.

Recent records from the coroner's court have borne lugubrious testimony to the frequency of deaths after anæsthesia. I know that there have been an alarming number of sudden unexpected early post-anæsthetic asphyxial calamities in ear, nose, and throat cases, where an intratracheal anæsthetic has been used—usually following premedication with 'Omnopon' and scopolamine. I regard as deadly the combination of omnopon-scopolamine and 'Pentothal' with intratracheal anæsthesia by a laryngo-pharyngeal local anæsthetic in nose or throat cases; this sequence should be banished from the anæsthetist's armamentarium.

The early return of the cough reflex is all-important; the anæsthetist should know the exact duration of the local anæsthesia produced by the application of different strengths and amounts of solution to the laryngo-pharynx.

London, W.1. N. ASHERSON.

URTICARIAL REACTIONS TO PENICILLIN

SIR,—A number of points raised by Dr. Frankland in his letter of July 5 require further comment.

I must apologise for the confusion caused by my use of the terms penicillin X and penicillin Y. When I submitted my paper I used the terms penicillin A and B, and you, Sir, altered these to X and Y. They signified two different commercial preparations of penicillin of unknown composition and did not indicate any of the forms known in America as F, G, X, and K. I did not draw attention to this alteration, believing that the context made this clear, particularly as there is, as far as I am aware, no form known as penicillin Y.

From his further remarks I gather that Dr. Frankland believes that my pure penicillin was the commercial preparation known as "Crystalline Penicillin." This has a minimum potency of 1600 units per mg., which in recent batches has reached 1660 units per mg. This was not the case. As stated in my paper, I used a pure preparation containing 1666 units per mg. I cannot at present state the composition of this in terms of penicillins I, II, III, and IV, but since you suggested (*Lancet*, June 21, p. 877) that I had not entirely excluded the possibility of one of these being the cause of the allergy, I have inquired of the makers the nature of their preparations. This information is not yet available to me.

In view of the immediate skin responses, I cannot agree with Dr. Frankland that these cases were of the delayed type of allergy. It seems more likely that the clinical delay is an expression of the incubation period between first exposure to penicillin and the establishment of the allergic state, which, when established, is of the "immediate" variety. Prausnitz-Küstner tests were not carried out, but the results appeared sufficiently clear-cut to be worth reporting.

In conclusion, Dr. Frankland states that his results are at variance with mine. I have recently repeated these tests on a further case of penicillin urticaria with identical results. Both in this case and in the case reported, my findings were confirmed by independent observers.

Epsom. LOUIS STEINGOLD.

FILTHY RIVERS

SIR,—In your leading article (July 12) you made no mention of infantile paralysis. Many years ago my father, the late W. H. Elam, F.R.C.S., called attention to the association between this dread disease and the pollution of rivers.

My own experience, though much less than his, certainly confirms his views. I have found that young people, especially young adults, who contract infantile paralysis have in many cases been recently swimming in rivers. Recent work in the U.S.A. would certainly suggest polluted rivers as a fruitful cause of one of our most tragic diseases.

New Barnet. JOHN ELAM.

LACTIC-ACID INJECTIONS OF JOINTS

SIR,—Mr. Grant Waugh, F.R.C.S., of Sunderland, first began to use a solution of lactic acid for the treatment of osteo-arthritic joints about thirteen years ago. Some three or four times since then he has fully described in the medical journals the rationale of this treatment and his technique for various joints. Unfortunately the method has caught the public eye and much undesirable publicity has resulted. As always happens in such cases, the lay public have seen in these injections a cure-all for every form of arthritis and rheumatism. Mr. Waugh has never made exaggerated claims for it; he has, on the contrary, strictly limited what he considers to be its legitimate field of use.

Lactic-acid injections have been under intense investigation in the special clinic at the Royal Free Hospital for some two years. This clinic has had the advantage of the regular supervision and guidance of Mr. Waugh. Injections have also been extensively used during the year at the British Legion experimental unit at Arlesey, in the clinic at the British Red Cross Clinic for Rheumatism, and in private.

It had originally been intended to accumulate a large number of cases, watch them over a long time, and analyse them carefully as regards history, radiological appearances, and other factors. But, in view of numerous inquiries that have reached both the Royal Free Hospital and the British Legion, and in fairness to Mr. Waugh, it appears to us that a presentation of the figures as far as we have gone is now called for, and we give these without any attempt at a full statistical analysis.

We consider that, when a method such as Mr. Waugh's is introduced to the medical profession, the proper procedure is for someone to go over the ground covered by the author with full and loyal adherence to his recommended techniques. This has been achieved by regular contact with Mr. Waugh, and this critical survey of the results is entirely independent of his cases in Sunderland or in private.

It is hoped in due course to present results of all our cases in a detailed paper. We therefore reduced our questionnaire to the following simple form, sending it

THE PRESENT POSITION

At present 22 out of 29 metropolitan local authorities *pose of their refuse* entirely by controlled tipping; use this method for part of their refuse, and pulverisan and incineration for the remainder; 1 uses incineran alone; and 1 transports all its refuse to brickfields. e yearly amount of refuse before the war was about 50,000 tons; now it is about 820,000 tons; and it is pected to reach about 1,000,000 tons. The following ures show the extent to which the various methods of sposal were used before the war and now:

Period	*Controlled tipping*		*Incineration*		*Pulverisation*		*Transported to brickfields*
1938–39 ..	94%	..	3%	..	2%	..	1·7%
1945–46 ..	83·9%	..	11·4%	..	2·3%	..	2·4%

The removal of the refuse to the tips is very largely the hands of relatively few contractors. It is generally greed that controlled tipping, properly carried out, is e least objectionable and probably the most economic ethod. Instead of a declining proportion, the whole of ondon's refuse, apart from what is needed for brickaking, could be disposed of in this way, eliminating om the metropolis all incinerators.

THE GARCHEY SYSTEM

The quantity of refuse to be collected could be conderably reduced by the adoption of the Garchey ystem (*Journal of the Royal Institute of British Archicts* 1934, *Phœnix* 1934) and similar devices for the echanical destruction of refuse in blocks of flats. The archey system has been fairly widely adopted in France nd was installed with apparently satisfactory results in large housing scheme in Leeds just before the war.

The Garchey system eliminates the need for dustbins and ust collection and is an advance on dust chutes to basement ontainers which, because of their misuse, so often become nsanitary and a cause of complaint.

A glazed fitting takes the place of the ordinary kitchen sink and consists of an upper shallow tray fitted with a large detachable grating. (Washing up is done in a separate bowl.) The lower part of the fitting is a bowl sealed with a plug completed by a long tubular shaft with a handle at the top. The shafts acts as an overflow for surplus water in the bowl. There is a small trap on the plug.

Into this fitting all house refuse except newspapers, boxes, and tins is thrown; the grating is lifted and the waste contents fall into a soil pipe which runs to the basement, where it ends in a special sump.

The refuse is drawn from the sump along falling pipes to a container. The liquid in the pipes is drawn off from the container and discharged into the sewer, and further moisture is disposed of before the rubbish falls into a furnace, where it is incinerated.

The heat created raises the steam necessary to drive the plant and can provide central heating for the building. About 25% of additional fuel has to be added to consume the refuse, and it is estimated that the cost of converting refuse to hot water is 1*s.* 6*d.* a week per household.

The French *practice of building large blocks of flats* makes the installation of the Garchey system more easy than has been the case in England so far.

RECONSTRUCTION OF REFUSE SERVICE

The method of collection and disposal of London's refuse today has many disadvantages. There is a multitude of collecting agencies with different standards of efficiency, some of them anachronistic. There is no central agency to deal adequately and economically with the refuse. The requirements put forward in 1914 at the Westminster conference for immediate action, though no longer adequate, have not yet been implemented, and it was left to voluntary collaboration of the London boroughs to implement the recommendation made in the Dawes report that a common cleansing organisation should be established with adequate powers to serve London and the thickly populated districts on its fringe. Such voluntary collaboration has not been forthcoming.

The institution of a central cleansing authority would be particularly opportune today. Vast housing programmes make possible the planning of the collection of refuse on hygienic lines; changes in local government offer a unique opportunity for imaginative administrative action; and the transfer of hospital services from the municipalities to regional boards is an opportunity for joint action between the London County Council and the municipalities of the surrounding areas for coördinated action on health matters beyond hospital organisation.

It is for administrators to decide whether an ad-hoc body consisting of the interested authorities and embracing Greater London should be established, or a statutory organisation created. Such a body should have statutory powers to acquire low-lying land for reclamation, to acquire and operate barges, trucks, and all other apparatus and equipment necessary for its work, to set up a permanent research station, and to lay down minimal and optimal requirements for the collection of refuse in newly constructed houses and flats. Meanwhile the amenities of the countryside and Greater London, no less than the needs of the metropolis, call for the solution of difficulties that have remained unsolved over a generation.

Housing in Birmingham

Like other cities, Birmingham undertook a rehousing programme at the end of the war; and a complete survey[1] made in 1946 displays alike the problems and the opportunities. Whereas a previous survey, ten years before, dealt only with "working-class houses," this time every dwelling in the city, including staff quarters in hotels and hospitals, was covered.

In all, 286,869 houses, or their sites, were visited, but 3258 were unoccupied—1916 because of war damage. The number of occupied houses in the city is therefore 283,611, and these are inhabited by 299,144 "family units."

Overcrowding was assessed in two ways: taking the standard of the Housing Act of 1936, overcrowding amounted to 1·92%; but if living-rooms used for sleeping purposes were left out of account, the figure was 11·26%. Back-to-back houses numbered 29,182; those without a separate water-supply 6429; those without a separate water-closet 34,965; those without bathrooms 142,523; and those without gas or electricity 417.

Trends since 1936 are in some ways unexpected. In the houses surveyed then taken as a whole, 3·77% *of families were overcrowded on the Housing Act standard*; and among families in the corporation housing estate, 8·75% were overcrowded. In 1946 overcrowding in the corporation estate had risen to 5·40%. A number of things have been responsible for this increase: families have grown; children have married and had children of their own; some families have moved in during the war, and others have come to the estate from the centre of the city; husbands have returned from war service; and building has been at a standstill. The 1946 figure for the city as a whole cannot be compared, of course, with the 1936 figure, when only working-class dwellings were covered. Moreover, warfare destroyed more of the small working-class dwellings than of the larger houses. Dr. H. P. Newsholme, the medical officer of health, estimates that, in comparable types of house to those surveyed in 1936, the overcrowding is now worked out suggest that the proportion may possibly be even higher. Dandy[2] concluded that more than half could be diagnosed in this way, so it would be interesting to know Mr. Creer's percentage of accurate diagnoses from straightforward radiography.

---

[1] Report of the Medical Officer of Health on the Housing Survey, 1946. City of Birmingham Public Health Department. Pp. 31.

On the other hand, it must be recognised that technical errors, such as inaccurate centring or faulty positioning of the patient, may produce very misleading radiograms. With imperfect technique the radiologist may well be somewhat more hesitant in his diagnosis than the orthopædic surgeon who, on the strength of his clinical investigation, may be tempted to read more from the radiogram than is justified.

One has to be equally careful in localising a disk protrusion largely on the strength of a radiogram. In double disk lesions, for example, only one intervertebral space may show radiographic signs of a disk protrusion. This can at times be most misleading, and, at the present stage, it is doubtful whether the radiogram always indicates accurately which disk is affected and giving rise to disability.

Clinical examination with corroborative straightforward radiography enables us to diagnose about 98% of all disk protrusions. Luckily, myelographies for the diagnosis of disk lesions have been largely abandoned, for, they are time-consuming, harassing to the patient, and, in Dandy's words, "They just don't make sense."

St. Peter's Hospital, Chertsey, Surrey. H. W. GILLESPIE.

SIR,—Mr. Burns and Mr. Young, in their zeal to describe unusual types of prolapsed disks, have omitted from their article (May 10) a description of the usual type. This forms, as Mr. Charnley has said (June 28), a sessile bulge at the level of the disk space.

I have found in seven cases pedunculated disks at a different level from the disk space as described by Burns and Young; sometimes they were posterior to the vertebral body, while sometimes they presented into the foramen along the course of the nerve-root. I have not yet met the lesion of the annulus fibrosus where "the torn piece of annulus can swing in and out, mimicking a torn cartilage of the knee."

I cannot agree with Mr. Creer (July 12) in his reliance on a straightforward radiogram for localising the lesion. One of the greatest contributions Burns and Young have made, in my opinion, is in pointing out that one can dispense with radiograms as a method of localisation.

Norwich. H. A. BRITTAIN.

CALORIE INTAKE IN HOT PLACES

SIR,—Your annotation of May 24 (p. 720) implies that our data[3] not unexpectedly show that in colder climates men consume an increased proportion of fat in their diet. This is not so. Table I in our paper demonstrated that, *regardless of environment*, the percentage of fat voluntarily chosen from the rations was "high" by traditional criteria. For example, in temperate climates 43% of the calories were provided by fat, while in the arctic this percentage was slightly reduced to about 40% of the calories.

We are intrigued by the fact that young men living on a luxus diet choose to eat what by usual standards are rather high fat intakes.

ROBERT M. KARK
Tinley Park, Illinois. ROBERT E. JOHNSON.

CLICKING PNEUMOTHORAX

SIR,—Dr. Thompson may care to have my further observations on a subject which interests us both (*Lancet*, May 10, p. 630, and May 31, p. 766). I have now had a thoracoscopy performed, but I regret, on his account, that since no adhesions were found the effect on the clicking sensations of pneumolysis could not be observed. It was postulated that there was probably a small adhesion anteriorly, near the chest-wall, out of view. At any rate, now that I am having large refills, these annoying and interesting sensations have disappeared. I have no doubt myself that a small adhesion is present—so small that it does not present adequate collapse of the lung. MEDICO.

Public Health

COLLECTION AND DISPOSAL OF LONDON'S REFUSE

MAX SORSBY
L.M.S.S.A.
LONDON COUNTY COUNCILLOR

THE collection and disposal of London's refuse have been under consideration for more than thirty years by many authorities, including the Ministry of Health and its predecessor, the Local Government Board; but, though some improvements have been effected, the reconstruction of the entire service, repeatedly recommended, has not yet been carried through.

Londoners can still see house refuse carried through houses in wicker baskets or dilapidated uncovered bins and tipped into uncovered carts. The possible danger from these insanitary methods to the health of the public and of the men who handle the refuse is not sufficiently recognised. The disposal of the collected refuse is an even more serious problem, and the refuse dumps in particular have attracted much unfavourable comment.

Refuse disposal used to be, and to some extent still is, little more than a haphazard dumping of refuse by one local authority into the area of another local authority. This uncontrolled dumping led the Westminster City Council to convene in May, 1914, a conference which called for concerted action by the London boroughs. In the report (published in 1920) crude dumping was deprecated and alternative methods were discussed.

In 1922 the Ministry of Health, spurred on by many complaints, called a conference of the London County Council and the metropolitan borough councils. The outcome was a letter addressed by the Ministry to all the authorities concerned, setting out the measures commonly referred to as "controlled tipping" and now followed throughout the country. The Ministry also pointed out that "it must not be taken for granted that, even with the adoption of these precautions, tips can be made absolutely sanitary, or that this method of disposal of refuse is one that can be regarded as wholly satisfactory." This note of caution was justified by the increasing and ever more insistent complaints made by those authorities whose areas continued to be used as dumping-grounds.

Dawes, in his report of 1929, noted that more than 29 different authorities were responsible for the cleansing of London. Most of them had to transport the refuse sometimes over considerable distances and generally in a crude state and in uncovered wagons; and in all but three of the dumps to which this refuse was transported conditions were unsatisfactory, and some of the dumps were not far distant from dwellings. He concluded that the service was for "the most part unsatisfactory and in a number of cases manifestly unsanitary . . ., from the technical point of view, the system is wrong in principle, and that the only way of securing effective refuse disposal arrangements for London is by establishment of a common cleansing organisation."

The Ministry of Health (1930) confirmed the findings in the Dawes report, and agreed that there should be central service controlled by one authority for the disposal of refuse from London, but held the view that a voluntary scheme would be preferable to a compulsory measure.

The Metropolitan Boroughs' Standing Joint Committee (1934) emphasised the need for coöperation between the borough councils, and called for action on unsatisfactory refuse tips and to ensure that barges, trucks, and other vessels conveying refuse should be covered and should not be used for foodstuffs.

ra food for manual workers, extra food to be pro- ced from our own land are all demands being made, l demands whose importance will become more clear ring the autumn, when our economic resources may at their ebb.

MEDICUS, M.P.

QUESTION TIME

Regional Hospital Boards

olonel M. STODDART-SCOTT asked the Prime Minister if, view of the fact that in the appointment of regional hospital ards, members of the House of Commons from one party y had been appointed, although members from other parties l similar qualifications of hospital work administration d management, he would set up a select committee to nsider the effect of such political appointments on the spital services of this country.—Mr. C. ATTLEE replied: repudiate the suggestion that these appointments are litical; examination of the boards' membership will prove at persons with suitable experience have been chosen thout any shadow of political exclusiveness. The last rt of the question, therefore, does not arise.—Colonel ODDART-SCOTT: Is the Prime Minister aware that 6 mem- rs of this House, all members of the Labour party, and 4 embers of the House of Lords, none of whom is Conservative, ve been chosen to sit upon these boards; and is he further vare that such political appointments will mean an inevitable ange in these hospital boards after the next general election, d will be to the detriment of the hospital service?—Mr. TTLEE: I do not think that the hon. and gallant gentleman s his facts correct. I believe that there are 5 members om this side of the House, and from the House of Lords ere is Lord Cunliffe, the Earl of Cranbrook, and Lord enley, who are certainly not members of this party, and rd Eustace Percy, a very eminent Conservative. I really think it is unjustifiable to complain just because now, ter many years, some Labour people are appointed to these rious boards.

Sir HENRY MORRIS-JONES: Is the Prime Minister aware at some of the names on these boards, particularly in orth Wales, have been received with perplexity, and may ask whether he can tell the House why people who have ven their lives to hospital service are omitted?—Mr. TTLEE: Perhaps they are too old.

Three in One

Commander A. H. P. NOBLE asked the Minister of Defence hat progress had been made towards merging the three ervice medical branches.—Mr. A. V. ALEXANDER replied: his question is still under examination. I ought, however, make it clear that it has not yet been established that e complete merger of the three medical services is to be referred to the alternative of the maximum degree of ordination between those services.

Colonel STODDART-SCOTT: Does the Minister realise that e merger of these services will result in great economy in ilitary man-power, and will he consider at the same time e merger of the three nursing services?—Mr. ALEXANDER: have been looking into the question of economy of man- ower that might be effected by the merger. Not only I, ut other departments which have examined the matter, far have not been convinced of the actual economy to e effected. As I say, however, the matter is still under nsideration.

Employment of Disabled

Replying to questions, Mr. G. ISAACS stated that on May 19 e number of disabled persons recorded at employment changes as unemployed was 64,754. The total number of ersons on the register of disabled is 700,000.

National Hearing-aid

Sir E. GRAHAM-LITTLE asked the Lord President of the ouncil if, in view of the claims that the national hearing-aid as superior in performance to any other hearing-aid yet ade, he would publish, for the information of the deaf ublic and other interested persons, the results of the National hysical Laboratory performance tests, or any other per- rmance tests carried out on the national hearing-aid.— Ir. H. MORRISON replied: Information about this hearing- id, including particulars of performance tests, is given in he report of the electro-acoustics committee of the Medical esearch Council. This is now in the press and will be issued y H.M. Stationery Office in due course.

Notes and News

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION

THIS association's fifth congress, held at Amsterdam between June 24 and 28, was attended by 350 delegates from sixteen countries. The congress was opened by the Minister of Social Affairs, with Miss L. Martindale, F.R.C.O.G., the president, in the chair. At the council and general meeting Dr. A. Ruys, professor of microbiology in the University of Amsterdam and a leading figure in the resistance to German occupation, was unanimously elected president for the next three years. The following vice-presidents were elected: Dr. Braestrup, Denmark; Dr. Eriksson-Lihr, Finland; Professor Gauthier-Villars, France; Dr. Edna Guest, Canada; Dr. Miloshevitch, Poland; and Dr. Stimson, U.S.A. Dr. Doris Odlum was re-elected hon. treasurer, and Mme. Montreuil Straus hon. secretary. It was decided to hold the next council meeting in Finland and the next congress in the United States; the office is to remain in Paris for the next three years.

At the scientific sessions the association discussed the responsibility of medical women in the reconstruction of the world. The wide variation in their status and influence in different countries was emphasised. The proportion of women in the medical profession ranges from 1·5% in Belgium to 25% in Poland. Canada has 3%, France 5%, U.S.A. 5%, Sweden 7·5%, Norway 8%, Denmark 9·1%, Holland 10%, Hungary 10%, Great Britain 14%, Czechoslovakia 15%, and Finland 17%. In Poland, where all posts are open to them, women doctors exert great influence; but in some countries there is still prejudice against their appointment to senior hospital posts. It was agreed that in post-war reconstruction men and women should take equal responsibility. Hitherto the bulk of the work has been done by men, and one delegate suggested that women are sometimes too timid to make their voices heard. A strong effort by women themselves is needed to bring home to the governments the valuable part that women doctors can play in reconstruction.

PLANT CHROMOSOMES

UNTIL fossils were studied scientifically, attempts to classify plants and animals rested on comparison of the macroscopic characters of existing types, and the origins of cultivated forms were traced mainly through their similarities to known wild forms. Investigation of the geological record led to big advances in knowledge, and still greater strides were made with the coming of knowledge on the mechanics of heredity. Only in recent years, however, has it been realised that the study of the chromosomes, the carriers of the heredity factors, can throw light on the relations between familial types, and that the counting of chromosomes may enable us to distinguish the more recent from the more primitive.

Before any attempt can be made to use such a criterion in a revised system of classification an immense mass of data on chromosome numbers must be collected. Fortunately, during the past twenty years workers in many countries, in the course of cytological studies often undertaken for quite other purposes, have recorded chromosome numbers in a great number of plants; and since much of this work has been in connexion with plant-breeding much of the information relates to plants of economic or æsthetic importance.

Darlington and Janaki Ammal[1] have performed a bibliographical feat in collating all these scattered records, and have compiled an imposing list of known chromosome numbers. Arguing from their wide experience in the mechanics of polyploidy that in general those species, within a genus, which possess the smaller chromosome numbers will represent, or be nearest to, the primitive forms, and that those with higher numbers will probably derive in a logical manner by polyploidy, they have put forward a tentative revised classification of the higher plants. Their book is thus both a list of chromosome numbers and a classification which takes cognisance of these numbers and throws light on the origins of cultivated plants. The geographical relationships, possibly suggested by the word "atlas" in their title, are only a secondary, though derivable, implication.

---

[1] Chromosome Atlas of Cultivated Plants. By C. D. DARLINGTON, F.R.S., and E. K. JANAKI AMMAL, D.SC. London: Allen & Unwin. 1945. Pp. 397. 12s. 6d.

about 2·52%; so it may be fairly claimed that overcrowding has been reduced by a third in the ten years. The housing schemes of the city council have certainly played an important part in this improvement, though reduction in the size of families must also be a factor. He notes that when married couples have to share a house with their parents or others, though they may not be overcrowded by any official standards, they are sometimes irritated and unhappy.

In the 1936 survey, overcrowding in the central wards was 8·7%, as compared with 3·3% in 1940; in the middle ring the figure has fallen from 2·7 to 1·3%, and in the outer ring from 2·0 to 1·9%. The excess of families over houses is 15,533, and 25,000 houses are due for demolition. The net housing requirement cannot be exactly assessed, because much could be done by redistribution. Moreover, when an overcrowded family is moved into a new house, their former house can be used for a smaller family. The number of new houses needed is therefore smaller than the number of cases of overcrowding: the Ministry of Health put it at 55% of the overcrowding figure. Dr. Newsholme thinks that, quite apart from future slum clearance and redevelopment, some 7000 houses are needed to meet this due proportion of the present excess of families over houses, plus some 18,000 to get rid of an equivalent proportion of bedroom overcrowding, plus 20,000 houses, to be built over ten years, to meet natural increase of population. The last two figures overlap to some extent.

Smallpox

Willenhall.—The first patient in this district, which is near Bilston, was removed on July 9. She is aged 19 and unvaccinated. She sickened on July 3 and a confluent rash appeared on July 6. Numerous contacts are under surveillance.

At *Bilston* the diagnosis in a boy, aged 10, removed on July 3, has now been confirmed. Modified rash appeared on July 2. He had been vaccinated for the first time on June 23. Contacts are still under surveillance.

Barnsley.—The daughter and son-in-law of the woman, aged 62, admitted to the smallpox hospital on June 30 were removed on July 11 when smallpox rashes appeared. Both had been vaccinated on July 2, one primarily and the other after an interval of 30 years.

Southampton.—The suspected case removed from the *Carnarvon Castle* on July 8 is suffering from chickenpox.

The *Times* of July 14 reports that the first case in Dublin since 1900 was discovered on board an American ship which has arrived from California.

Up to July 12 there had been 10 cases of smallpox in two generations in Calais, and 1 in Lille, secondary to the focus in Calais.

Poliomyelitis

The Registrar-General's returns for the week ended July 5 record 79 notifications, compared with 9 in the corresponding week of 1946. This figure has rarely been exceeded since the disease became notifiable in 1912. The maximum recorded incidence was in 1938 (1489 cases); in the first twenty-seven weeks of that year 127 cases were notified. The figures for the corresponding periods of 1946 and 1947 have been 206 and 435 (uncorrected).

The disease is widely spread. Notifications in the week ended July 5 were received in 65 sanitary districts, and were mainly singletons. However, since July 5 multiple cases have been reported from several districts, and in all probability a "new high" occurred in the past week. An unprecedented prevalence is to be expected.

Acute onsets with sharp meningeal reactions, leading to a diagnosis of meningitis or meningo-encephalitis, appear to have been a feature in the present outbreak. In such cases the preparalytic stage lasts some days, and it may be presumed that infectivity is greatest in this period. Early isolation on suspicion before the onset of paralysis is probably the most effective action towards preventing the spread of the disease.

Bulbar and respiratory paralysis is unusually frequent, and respirators are in demand. In one extrametropolitan borough 7 children have been admitted to the isolation hospital since June 18, 5 of them in the first eleven days of July; of these, 2 required treatment in respirators. Tonsillectomy had been performed on 1, aged 4 years, a fortnight before signs of bulbar paralysis appeared. It has been advised[1] that when poliomyelitis is prevalent nose and throat operations should, if possible, be postponed.

An assistant master at a preparatory school at Aldenham, Herts, has died of poliomyelitis, and another master and a boy have contracted the disease. The school has been closed.

During the week ended July 5, 64 cases of cerebrospinal fever were notified. The increase in notifications, contrary to the expected seasonal decline, may be an expression of the increased incidence of anterior poliomyelitis with well-marked meningeal signs at the onset.

PLAGUE IN EAST PRUSSIA.—Epidemic bubonic plague appeared in Königsberg during June and has caused many deaths among the civilian population.

Infectious Disease in England and Wales

WEEK ENDED JULY 5

Notifications.—Smallpox, 3; scarlet fever, [illegible]; whooping-cough, 2240; diphtheria, 188; paratyphoid, 8; typhoid, 15; measles (excluding rubella), 10,[illegible]; pneumonia (primary or influenzal), 353; cerebrospinal fever, 64; poliomyelitis, 79; polioencephalitis, 9; encephalitis lethargica, 4; dysentery, 57; puerperal pyrexia, 144; ophthalmia neonatorum, 61. No case of cholera, plague, or typhus was notified during the week.

Of the 3 smallpox cases, 2 were notified at Bilston, Staffs, and 1 at Barnsley, Yorks.

Deaths.—In 126 great towns there were no deaths from enteric fever or scarlet fever, 2 (1) from diphtheria, 5 (1) from measles, 11 (1) from whooping-cough, 52 (4) from diarrhœa and enteritis under two years, and 5 (0) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 238 (corresponding to a rate of 25 per thousand total births), including 31 in London.

Parliament

ON THE FLOOR OF THE HOUSE

THE Indian Independence Bill came before the House for discussion on July 10 and passed its second reading. So after over 250 years a British chapter of Indian history is ending. The power of government in India is to be handed over to the two Dominions by Great Britain on August 15, and it is significant that the sobering effect of responsibility on India has been great. It is now clear that the British business community will remain, and it is hoped that many British civil servants, doctors, and perhaps soldiers will remain too in the employ of one or other of the Indian governments. The great problems of India are food, health, and agriculture. Industry on any very large scale has yet to be developed. How will India deal with her recurrent famines and epidemics? How will India raise the standard of health of her peoples? There certainly will be in India vast scope for great health and nutritive changes.

Turning from East to West, Parliament has paid attention during the week to problems of the reconstruction of Europe. Can we reconstruct before the dollar line of credit runs out? Or must we willy-nilly get help from the Marshal offer on some new basis? That we shall need all our ingenuity in planning to keep our nation fit and well is clear. Extra food for children is honorary radiologist to the Queen Elizabeth Hospital. In 7 he was awarded the Robert Jones medal of the British Ortho- lic Association for his essay on Deformities of the Lumbo-sacral ion of the Spine. He is also author of *Radiology of Bones and ts*, and he has twice—in 1934 and again in 1943—delivered nterian lectures to the Royal College of Surgeons. In 1939 was elected a fellow of the Faculty of Radiologists, and he was first president of the British Association of Radiologists. In 1 he was elected F.R.C.P.

---

iversity of Manchester

On July 5 degrees were conferred on the new graduates ned in our issue of July 12 (p. 77). The degree of M.D. s also conferred on F. P. Ellis (gold medallist), R. W. rslem, A. I. Goodman, A. D. Leigh (in absentia), T. P. rell, and Isaac Sutton.

iversity of Glasgow

On July 9 the following degrees were conferred:

M.D.—Jean L. Buchanan, Ben Couts, Margaret S. Ferguson, enah J. M. Russell, Elizabeth B. S. Scobbie, A. B. Semple, via J. Strachan, A. M. W. Thomson (with commendation); T. Boyd, James Caldwell, Robert Hillman, W. B. McKenna, L McNeil, Kwao Sagoe, J. F. Swan.

M.B., Ch.B.—Anne S. McNaughton (with honours); A. D. y, W. P. Crane, Robert Pirrie, W. A. J. Crane (with commenda- n); H. M. Adam, James Aitken, K. J. Alexander, A. C. Anderson, an Angus, A. S. Arnell, John Barr, J. B. Bell, Alexander Boyd, W. Boyd, J. M. Boyd, Anne N. M. Brittain, J. O. Brocklehurst, H. Brown, James Brown, John Brown, R. W. Bryson, Margaret S. Calder, Margaret Cameron, M. W. Clark, John Craig, A. S. llen, John Currie, Pamela A. Davies, E. D. B. Denovan, M. B. vertie, Irene E. Donald, Lilian I. Donald, Robert Donald, A. N. wie, Alison M. T. Drimmie, Margaret B. Eadie, Alexander rley, W. R. Falconer, Margaret M. Ferguson, J. J. Flanigan, H. S. Forrest, W. T. Fullerton, Rosamund M. H. Fulton, L. A. landers, W. J. Gordon, Archibald Guinea, Jessica M. S. Hamilton, S. Happel, L. L. D. Hodge, J. R. R. Holms, J. G. Inglis, W. T. ine, David Irwin, Bernard Isaacs, Agnes B. Johnstone, G. D. , J. M. Kay, Teresa Kelly, J. W. Kerr, Agnes F. W. Laughland, ce F. P. Lightbody, G. S. Macadam, Ian McAlpine, H. S. Callum, Lorna G. Macdougall, Christine R. Macgregor, Susanne M. cGregor, Iain MacIntyre, Sheila Macintyre, D. M. McKean, D. McKee, D. I. MacKenzie, S. D. MacKenzie, William McKerrell, n I. Mackinnon, Alastair MacLean, A. I. MacLeod, R. C. Macleod, B. McMillan, A. L. McNab, D. L McNab, Alan Macpherson, stair Mair, Helen M. Mair, D. B. Meek, J. C. Merry, J. S. Moffat, mes Morgan, Agnes A. M. Muir, Alexander Munn, D. B. Neilson, rjorie G. Nisbet, Mary K. P. Pollock, F. B. Proudfoot, Helen J. G. msay, D. A. Rice, Sheila C. S. Richard, A. A. Robin, Thomas ssell, W. I. Russell, Goldwyn Sclare, Alison Shannon, James npson, J. T. Smith, James Stanners, Isobel M. W. Stark, James ewart, Margaret P. Stewart, Robert Strang, A. M. P. Thomson, H. Thomson, W. O. Thomson, William Todd, David Turnbull, exander Urquhart, W. B. Waddell, Joan L. Wakeham, Mary C. allace, Camilla M. Walton, J. A. Watson, A. A. Wilson, T. A. lson, C. M. Wylie, F. O. Young, M. A. C. Young.

niversity of Dublin

On July 2, in connexion with the Rotunda bicentenary lebrations, the honorary degree of M.D. was conferred at inity College on Sir Eardley Holland, F.R.C.O.G., and Dr. enry Stander, obstetrician and gynæcologist-in-chief to w York Hospital.

oyal College of Surgeons of England

At a meeting of the council held on July 10, Sir Alfred ebb-Johnson was re-elected president for the ensuing year d Sir Cecil Wakeley and Mr. L. E. C. Norbury were elected ce-presidents.

The council issued invitations to 21 dental surgeons to rve as the first members of the board of the faculty of ntal surgery of the college, and the following were invited become the first 18 fellows in dental surgery:

H. F. Humphreys, O.B.E., M.C., Harry Stobie, F.R.C.S., A. D. lward Shefford, O.B.E., W. K. Fry, M.C., M.R.C.S., Vivian reenish, Major General A. B. Austin, C.B., Surgeon Captain James homson Wood, C.B.E., Edward Samson, A. C. Deverell, Air Com- odore G. A. Ballantyne, C.B.E., D.F.C., F. S. Warner, R. V. radlaw, M.R.C.S., H. A. Mahony, F. C. Wilkinson, M.D., E. W. sh, C.B.E., M.D., T. T. Read, F.R.F.P.S., W. G. Senior, O.B.E., T. Roper-Hall, M.B.

The following were elected lecturers for the ensuing year:

Hunterian professors: Mr. A. W. Badenoch, Congenital Obstruc- on of the Bladder Neck; Mr. A. D. Beattie, Treatment of Peptic lcer by Vagotomy; Mr. Denis Browne, Hare Lip and Cleft alate; Mr. Murray Falconer, Lumbar Intervertebral Disk Surgery; r. Hassan Ibrahim, Bilharziasis and Bilharzial Cancer of the ladder; Mr. Robert Guy Pulvertaft, Repair of Tendon Injuries the Hand; Mr. Victor Riddell, Carcinoma of the Breast; Mr. rancis Stock, Hypertension; Mr. A. Hedley Visick, Failure after astrectomy; Mr. Stanley Way, Lymphatic Drainage of the Vulva nd its Influence on the Radical Operation for Carcinoma; Mr. M. C. Vilkinson, Skeletal Tuberculosis; Harold Wookey, Malignant isease of the Pharynx and Œsophagus. *Arris and Gale lecturers:* r. E. M. Darmady, Acute Uræmia; Mr. Leon Gillis, Arm Amputa- ons, Cineplastic Surgery, and Arm Prostheses; Mr. H. F. Lunn, natomy of Hernia. *Erasmus Wilson Demonstrators:* Mr. V. achary Cope, Mr. R. J. McNeill Love, Mr. Philip Mitchiner, Dr. W. Proser, Mr. R. W. Raven. *Arnott Demonstrators:* Dr. R. J. ast, Mr. Lunn.

A diploma of fellowship was granted to D. P. Robertson and a diploma of membership to A. J. Ruzicka.

The following diplomas were awarded jointly with the Royal College of Physicians:

D.P.M.—E. H. Cranswick, J. A. Crawford, P. B. de Maré, J. J. Fleminger, E. H. Hare, A. B. Hegarty, R. F. Hobson, J. G. Howells, Wallace Ironside, John Johnston, G. N. Jones, V. L. Kahan, Julian Katz, L. G. Kiloh, A. B. Kinnier Wilson, C. C. Lack, A. F. McLean, Morris Markowe, D. A. R. Pond, K. C. Royes, Peter Sainsbury, A. B. Sclare, Salo Tischler, P. M. Turquet, A. H. Williams.

D.L.O.—James Ackerley, J. N. Appleton, L. F. Day, P. F. King, J. A. Langille, J. M. Marquard, P. K. L. Orton, C. C. Ring, R. V. Tracy-Forster, K. L. Wilson.

D.I.H.—W. E. Broughton, Caroline J. Brown, Alan Butterworth, J. V. Manning, H. B. Melzer, Niaz-ud-Din, Dorothy Williams.

D.A.—N. C. Smiedt.

Order of the Hospital of St. John of Jerusalem

Promotions and appointments recently announced include:

Knights.—Major J. F. Hamilton, M.D., R. D. Thomas, L.R.C.P.E., Air Vice-Marshal Sir William Tyrrell, K.B.E., D.S.O., M.C., M.B.

Commanders.—F. L. Richard, M.B., P. S. Selwyn-Clarke, C.M.G., M.C., F.R.C.P., Brigadier G. S. McConkey, O.B.E., M.D., Surgeon Rear-Admiral A. E. Malone, C.B., M.B., Surgeon Rear-Admiral H. M. Whelan, M.R.C.S. (since deceased), C. C. B. Gilmour, C.B.E., M.B., J. M. Hermon, M.D., G. P. Huws, M.B., Major G. S. Phillips, M.D., Prof. N. Hamilton Fairley, C.B.E., F.R.C.P., F.R.S.

Officers.—Lieut.-Colonel F. A. Bevan, M.B., Lieut.-Colonel T. F. Briggs, M.R.C.S., Anacletus Byrne-Quinn, M.B., J. A. L. Roberts, M.B., Major T. W. Carrick, R.A.M.C., Lieut.-Colonel C. P. Stevens, M.B.E., M.B., Ivy MacKenzie, M.D., Surgeon-Captain L. F. Strugnell, M.B., Surgeon-Captain R. C. May, O.B.E., M.C., M.R.C.S., Kypros Chrysanthis, M.D., H. G. Davies, M.R.C.S., Lieut.-Colonel M. P. Atkinson, I.M.S., H. H. Warren, M.B., T. W. David, M.R.C.S., G. R. Jones, M.D., G. P. Williams, M.R.C.S., Colonel C. R. Croft, M.D., Surgeon Captain K. D. Bell, M.R.C.S., Colonel T. J. L. Thompson, O.B.E., M.C., M.B., J. W. Reid, M.D., C. A. Bence, M.R.C.S.

Royal Society of Edinburgh

On July 7 Sir Edward Appleton, D.SC., F.R.S., Sir Alexander Fleming, F.R.C.P., F.R.S., and Sir Arthur MacNalty, F.R.C.P., were elected honorary fellows of the society.

Food and Drugs (Milk and Dairies) Act, 1944

The Minister of Health, after consultation with the Minister of Agriculture and Fisheries, has decided that in view of the many technical difficulties involved it will not be practicable to bring this Act into operation this year.

Rheumatology Congress

The first European Congress of Rheumatology will be held at Copenhagen and Aarhus from Sept. 4 to 8 under the presidency of Prof. Cai Holten. The topics chosen for discussion include the ætiology and pathogenesis of rheumatic fever and rheumatoid arthritis, the treatment of rheumatoid arthritis, the social importance of the rheumatic diseases, and bioclimatological problems of rheumatology. Further information may be had from the Empire Rheumatism Council, Tavistock House, London, W.C.1.

Dr. Jessie Macgregor Prize and Lecture

Applications are invited from medical women who are graduates in medicine of the University of Edinburgh or who have taken the Scottish triple qualification, after studying medicine for at least one year in Edinburgh, for this prize which is of the value of £50. It is awarded for original work in the science of medicine, which may be published or unpublished, but must not have been published earlier than three years ago. Applications must reach the convener of trustees, 9, Queen Street, Edinburgh, 2, not later than July 31.

Medical Sickness, Annuity and Life Assurance Society

On July 15, at the 62nd annual general meeting of this society, Mr. R. J. McNeill Love, F.R.C.S., the chairman, reported that membership now exceeded 10,000 and that the new business written in 1946 was a record in their history. New policies were issued to secure sickness and accident benefit of over 6600 guineas per week and life assurance of over £500,000. The funds of the society had increased last year by £228,000 and now stood at nearly £3½ million, of which half are in British Government securities. The last valuation took place during the war and a declaration of a bonus on the life fund was therefore deferred. The directors, Mr. Love announced, now felt justified in recommending a reversion bonus of 15*s.* per cent. for each of the ten years 1937–46, a rate which it was hoped to maintain. Policies for sickness and accident insurance had received a bonus at a reduced rate in 1941, but it had now proved possible not only to restore the pre-war rate but slightly to improve it, and the directors were recommending a reversionary bonus on the A/65 and A/60 tables at the rate of 16*s.* for each one guinea per week insured.

A brilliant introduction by Darlington explains the underlying theories and correlates these studies with the classical work of Vavilov on plant origins based on genetic investigations. The value of the book for reference is increased by abbreviated information on the uses of the plants listed and on their geographical distributions. Of more questionable value is the addition of popular names. Many widely accepted popular names are omitted, while others are included for which the justification is, to say the least, obscure. The book will, however, become a standard reference work for all plant-breeders and geneticists and for many horticulturists.

CONDENSED MILK FOR INFANT FEEDING

The Ministry of Food inform us that the allowances of full-cream condensed milk for infant feeding, obtainable on a doctor's certificate from food offices, without surrendering points, are as follows (see The Lancet, June 14, p. 853):

Age of infant	*Sweetened (tins per month)*	*Unsweetened (tins per month)*
Under 5 months ..	Up to 10	Up to 18
5–6 „ ..	„ 11	„ 21
7–9 „ ..	„ 12	„ 23
10–12 „ ..	„ 13	„ 24

The tins of sweetened milk contain 1¾ pints (14 oz.)
„ „ „ unsweetened „ „ 2 pints (16 oz.)

The infant should also be able to obtain sweetened or unsweetened condensed milk on his own points coupons.

UFAW SUMMER SCHOOL

In nothing is a scientific mentality more patently needed than in the ethics of man's relations with animals. At one extreme there is the callousness engendered by the ghost of Descartes' theory of automatism, at the other the sentimentality that puts feeling in the place of knowledge. The Universities Federation for Animal Welfare has tried to put the whole subject on an objective basis. During the last week in September (20–27) Ufaw is holding a summer school for students of both sexes at the field study centre at Flatford Mill, in the Constable country. The programme will comprise lectures and discussions on the care of laboratory animals, whaling, methods of dealing with harmful animals, animal psychology, and various other topics; there will be visits to a bird sanctuary and other places of interest, social events, and free time for recreation (including bathing). It is hoped that a good number of medical students will attend. The inclusive fee is £2 12*s*. 6*d*., and details will be supplied by the secretary, Dr. F. Jean Vinter, 284, Regent's Park Road, Finchley, London, N.3.

VOICE-RECORDING IN SPEECH THERAPY

Northwood House Clinic, Leicester, is using gramophone records to detect progress in the treatment of defective speech. The patients' efforts at reciting nursery rhymes and making general conversation are recorded from time to time, and the recordings are played back after about three months to see whether treatment has resulted in improvement. The apparatus is supplied by Recorded Sound Ltd., of London.

MEDICINE IN THE THEATRE

In his play "The Gleam," lately running in London and now published in book form,[1] Mr. Warren Chetham Strode takes three quite pleasant acts to tell us that doctors work best when they have to be responsible to and for their patients. Here most of us will go all the way with him, but unfortunately he tangles this honest principle with a number of less evident propositions. The play is really a protest against the National Health Service, in which Mr. Strode sees a dangerous fettering of the doctor's liberty. Not content to let what facts there are speak for themselves, he unworthily presents all the opponents of his view who appear in the play either as mild knaves or honest fools. Moreover, he panders too freely to popular nonsense, with his talk of "surgeon's hands," and of the one man capable of doing successful "trepanation" in a given case. Without being particularly dramatic the play moves well from point to point, and the characters hold the interest. It is a pity, though, that he will not own what so clearly appears from the behaviour of his own chief character: that the Service makes the man only when the man is of poor quality. Where the men are good they make the Service, as the Navy brilliantly testifies. If we doctors are all that Warren Chetham Strode believes us to be, we have nothing to fear from the National Health Service.

CANADIAN RETIREMENTS

The University of Toronto's new age-limit of sixty instead of sixty-five for teachers in the faculty of medicine has led to several retirements in the four hospitals associated with the university. A complimentary dinner was given on June 11 by St. Michael's Hospital to Dr. Gordon S. Foulds, head of the department of genito-urinary surgery, who retires under this rule, to Dr. George Ewart Wilson, who leaves his post as surgeon-in-chief after a distinguished service of 20 years, and to Dr. N. D'Arcy Frawley, Dr. J. I. Robert, Dr. T. A. Robinson, and Dr. J. Harris McPhedran, former president of the Canadian Medical Association.

On June 12, at a dinner given by his colleagues in his honour, Prof. Duncan Graham, for 28 years Eaton professor of medicine, was presented with his portrait. Professor Graham is an honorary fellow of the Royal Society of Medicine, and a past president of the Royal College of Physicians and Surgeons of Canada and of the Canadian Medical Association. He is succeeded in his chair by Prof. R. Farquharson who is this year's president of the Canadian college and the chief consultant to the Royal Canadian Air Force.

On June 19, colleagues and graduates of the Gallie course in surgery gave a dinner to Prof. W. E. Gallie on his retirement from the professorship of surgery in the University of Toronto. Graduates of this course are granted a master of surgery degree by the university, and the surgeons-in-chief of six Toronto hospitals and the professors of surgery in two Canadian Universities are among its graduates. At the dinner Professor Gallie was presented with his portrait and with 52 essays on surgical subjects written by his colleagues and students. The collection, which filled three large volumes of typewritten manuscript, will be printed this year.

University of Oxford

In a congregation held on June 26 the degree of D.M. was conferred on J. M. Walker and G. S. Dawes.

Wellcome Laboratory of Human Nutrition.—The trustees of the will of the late Sir Henry Wellcome have offered the university £25,000 to buy and equip this laboratory on condition that the university provides £5000 annually for its upkeep during the next five years. The university has accepted the gift and is establishing the laboratory for the promotion of "the scientific study of human nutrition and for the collection and integration of existing knowledge." A reader in human nutrition with a stipend of £1100 a year is to be appointed.

University of Liverpool

At recent examinations the following were successful:

M.D.—T. C. Gray.

M.Rad. (*Part I*).—H. G. Frank, A. M. Fraser, J. R. Macleod, D. E. Paterson, I. Pierce-Williams, M. Robinson, H. L. Ross, G. B. Scarrow, W. I. Walker, J. Winter.

M.B., Ch.B.—F. G. Anderson, I. S. J. Crosbie, E. Dewsbury, Nancy V. Dilling, W. Ellenbogen, Sheila K. Frazer, G. I. T. Griffiths, Elizabeth Howorth, A. B. Jones, F. P., Lennon, G. L. Levy, G. E. Lucas, J. E. Riding, Audrey A. Shone, G. C. Sloo, M. H. Turner, L. C. Wolfman.

D.P.H. (*Part II*).—L. C. Allan, G. H. Ball, T. W. Brindle, A. M. Brown, Mary F Brownlie, W. F. Christian, D. J. Doherty, Catherine S. Ellams, D. J. Fraser, J. A. Gillet, Patricia F. M. R. Gould, M. D. Kipling, Ann Prysor-Jones, B. Pujari, K. V. Robinson, C. D. Rosenwald, K. C. Sahu, Irene W. Simpson, W. G. Tasker, A. R. Unsworth, E. Walker, S. R. Warren, E. B. Weeks.

University of Birmingham

Dr. T. L. Hardy has been appointed to the chair of gastro-enterology in the university. This is the first chair in the specialty to be established in this country. Dr. J. F. Brailsford has been appointed honorary director of radiological studies in living anatomy.

Dr. Hardy was educated at Radley College and Selwyn College, Cambridge. A graduate in arts and medicine of the University of Cambridge, he took the Conjoint qualification from the Middlesex Hospital in 1912. After service with the R.A.M.C. in the first world war he settled in consultant practice in Birmingham and was appointed to the staff of the Birmingham United Hospital. He has examined for the universities of Cambridge and Glasgow. In 1944 he delivered the Croonian lectures on Order and Disorder in the Large Intestine, to the Royal College of Physicians, to whose fellowship he had been elected in 1929. Dr. Hardy was one of the group who founded the British Society of Gastroenterologists in 1937 and until lately he was its secretary. His published work includes papers on hyperchlorhydria and ulcerative colitis.

Dr. Brailsford, who took his M.B. at the University of Birmingham in 1923, at present holds the appointment of radiological demonstrator in living anatomy in the university. He is also consulting radiologist to the Birmingham Accident Hospital and City Hospital.

Whether pulmonary cancer is on the increase or not s still debatable, but there is evidence that there is a eal increase. Everyone will admit that more cases are ecognised, a fact due to improved diagnosis and a greater awareness of the protean nature of the disease, but we do not know how many deaths formerly registered as pneumonia or bronchitis should have had pulmonary cancer recorded as the primary cause. Our knowledge of the early symptoms is still far from perfect, and many —apparently unimportant—are overlooked. The thoracic surgeon would willingly investigate fifty cases with negative result rather than miss one whose life may be saved by an early operation; and this can only be accomplished by radiography.

Pulmonary cancer is not necessarily a disease of old age; nor are wasting, cough, and hæmoptysis constant symptoms. Therefore it must not be assumed that youth, increase of weight, loss of cough, cessation of hæmoptysis, or absence of pain excludes a diagnosis of cancer. Nor in old age must the possibility be overlooked that cancer may be the primary cause of an unresolved pneumonia, bronchitis, or a failing heart. An important and common characteristic of these tumours is their insidious and silent growth. Several of our cases could have been diagnosed by radiography a year before pneumonectomy—eighteen months in one case. In short, whenever a chest condition does not fit an accepted pattern, cancer must always be suspected.

SYMPTOMS AND SIGNS

The symptoms are determined by the relation of the growth to the thoracic organs. A centrally placed mass may attain considerable size before producing severe symptoms, whereas a growth invading structures within the thorax or in the chest wall is more likely to produce early pain, cough, hæmoptysis, dyspnœa, or other definite symptoms.

Pressure Effects.—The chief symptoms are due to effects produced on the lung and bronchi, and vary with the type of invasion. Complete obstruction of a large bronchus, as happens with many squamous-celled carcinomata, leads to atelectasis peripheral to the block. Imperfect obstruction associated with infection causes suppuration to dominate the clinical picture, and lung abscess may result. A lung abscess may also result from breakdown of the tumour, in which case it is not segmental, it is radiologically eccentric to the main shadow, and it may have an irregular outline.

Invasion of the pleura produces pain or discomfort and effusion, which may be clear (when it makes diagnosis difficult), bloodstained, or purulent. Malignant cells may be found in the effusion. The growth tends to spread along the pleura rather than to the chest wall, but at the apex the ribs may be involved, producing a subcutaneous mass.

Interference with mediastinal tissue is usually the result of glandular involvement, which is most often seen with the oat-celled or undifferentiated type of carcinoma. The great veins may be obstructed, and paralysis of the phrenic or of the recurrent laryngeal nerves is one of the more common early signs. The tumour may infiltrate the pericardium, and then it tends to spread along the pulmonary veins; this may explain the auricular fibrillation which is found in some of these cases and may even be the first sign.

Metastases.—Metastasis is common in the oat-celled type of growth where the hilar glands are heavily involved, and a spread to adjacent nodes, such as the paratracheal, abdominal, and supraclavicular chains, makes surgery impracticable. Regional metastasis is less common in squamous carcinomata and adenocarcinomata, but in all cases secondary deposits may develop. There is a predilection for bone (ribs, vertebræ), and liver, skin, and brain may be involved. Secondary deposits in the brain should be carefully sought, because they can develop silently without producing any clinical neurological signs until the final stages. In our series three deaths within a few weeks of operation were due to this complication. Another unusual form of metastasis is invasion of the suprarenal glands, producing the Addisonian syndrome of severe asthenia, low blood-pressure, and bronzed skin.

Early symptoms are often slight and passed over as unimportant, especially if the patient is outside the traditional age-group for malignant tumours. If medical advice is sought, little or nothing may be detected, and weeks or months may elapse before the essential aid to diagnosis—radiography—is invoked. The classical signs, such as lassitude, persistent cough and sputum, dyspnœa, and loss of weight, *may, as already mentioned,* not develop for a long time. It has been estimated that, on an average, a year elapses between the initial symptom and the assessment for surgery. Delay occurs all along the line: the patient is slow in seeking medical advice; a period of conservative treatment or observation follows before there is any suspicion of something radically wrong; after admission to a general hospital the establishment of diagnosis may take some weeks; and further time may be lost before surgery is made available.

Only a few of the early symptoms have any apparent significance. Cough persisting after an "influenzal" attack, or associated with a supposed slowly resolving inflammation, may be accompanied by sputum. In middle-aged or elderly men with a chronic cough any alteration in its character should be suspect. Hæmoptysis, however, ought never to be ignored and demands immediate radiography. An initial hæmorrhage may not be succeeded by further bleeding for some time; but, if there is persistent and daily staining, carcinoma is the only condition, apart from hydatid disease, that can produce this. Shortness of breath on exertion, or transitory "asthma," may indicate the onset of atelectasis which otherwise remains symptomless. Pleuritic pain is often ignored if there is no subsequent effusion or disability. One interesting fairly early sign is pulmonary arthropathy, painful and disabling, mainly affecting wrists, fingers, and ankles. It is remarkable that pneumonectomy immediately relieves the pain and restricted movement of the joints.

Other signs and symptoms depend on the natural history of the disease: a secondary bronchiectasis will cause cough and sputum to dominate the clinical picture; and a pulmonary atelectasis will produce dyspnœa and distress until the body compensates for the disability.

When the patient is under treatment, symptoms may abate, and an increase in weight is common and misleading.

INVESTIGATIONS

Radiography.—The essence of early recognition of pulmonary cancer lies in radiography. Some cases are

American Surgeon Honoured

Dr. Philip D. Wilson, surgeon-in-chief to the Hospital for Special Surgery, New York, and clinical professor of orthopædic surgery of the College of Physicians and Surgeons, Columbia University, who organised and brought over the American Hospital in Britain in 1940, has been appointed honorary O.B.E.

London College of Osteopathy

A course in osteopathy is to be held at the college from Sept. 30, 1947, to July 6, 1948. The course is open to anyone holding a medical qualification registrable in Great Britain. Further information may be had from the secretary, 25, Dorset Square, N.W.1.

Institute of Almoners

In an account of its first full year's work, the report of the Institute of Almoners for 1946 records that the demand for qualified almoners continues to increase; during the year the institute was asked to advertise 294 posts, of which 99 had not previously been held by certificated almoners. The number of appointments made rose slightly from 208 in 1945 to 216 in 1946. Although the demand for qualified almoners is not being fully met, the number accepted for training cannot be greatly increased, because a social-science qualification and training in general family case-work are prerequisites, and in both these fields there is at present a serious shortage of training facilities.

Appointments

CANNEY, R. L., M.B. Camb., F.R.C.S.: general surgeon, Kent and Canterbury Hospital and Ramsgate General Hospital.
JONESCU, PIERRE, M.D. Jassy: physician, Rumanian Embassy, London.
SEYMOUR-JONES, J. A., M.B. Camb., F.R.C.S., D.L.O.: asst. surgeon, ear, nose, and throat department, Portsmouth and Southern Counties Eye and Ear Hospital.
SMALL, J. M., M.B. Birm., F.R.C.S.: asst. surgeon, neurosurgical department, Birmingham United Hospital.

Maudsley Hospital, Denmark Hill, S.E.5:

ANDERSON, E. W., M.D. Edin., F.R.C.P., D.P.M.: physician.
DAVIES, D. L., B.M. Oxfd, D.P.M.: senior registrar.
WARREN, WILFRID, M.B. Camb., D.P.M.: senior registrar.

Runwell Hospital, Essex:

CRANSWICK, E. H., M.B. Sydney, D.P.M.: asst. physician.
SCOTT, P. D., M.B. Camb., D.P.M.: senior physician.

Diary of the Week

JULY 20 TO 26

Monday, 21st

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
3.45 P.M. Dr. T. E. Barlow: Lungs.
5 P.M. Dr. C. E. Dukes: Pathology of Genito-urinary Tuberculosis.
INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray's Inn Road, W.C.1
4.30 P.M. Mr. W. M. Mollison: Nose, Nasopharynx, and Paranasal Sinuses.

Tuesday, 22nd

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. G. R. de Beer, D.SC.: Segmentation of Vertebrate Head.
5 P.M. Mrs. G. M. Bonser, M.D.: Pigmented Tumours of the Skin.

Wednesday, 23rd

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. James Whillis: Mouth and Pharynx. (First lecture.)
5 P.M. Mrs. Bonser: Experimental Cancer of the Bladder.

Thursday, 24th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. Whillis: Mouth and Pharynx. (Last lecture.)
5 P.M. Prof. R. J. V. Pulvertaft: Postoperative Pulmonary Embolism.
6.15 P.M. Prof. E. Sprawson: Foods and Feeding as they Affect Teeth and their Environment. (Charles Tomes lecture.)

Friday, 25th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. Albert Peacock: Nasal Sinuses and Cavity.
5 P.M. Dr. R. E. Rewell: Diseases Common to Man and other Animals.

Saturday, 26th

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.1
3 P.M. Colonel L. W. Harrison: Venereal Disease in the National Health Scheme.

Society of Public Analysts and Other Analytical Chemists

At a meeting of the physical methods group and the polarographic discussion panel of this society to be held at 3 P.M. on Friday, July 25, in the chemistry department, University College, Gower Street, London, W.C.1, Prof. J. Heyrovský will speak on Polarographic Analysis, and Dr. R. Brdička on Analytical Applications of the Cystine and Protein Reaction in Biochemistry and Medicine.

International Organisation for Standardisation

The first meeting of the council of the I.S.O. was held in Zurich from June 17 to 20. The council consists of the National Standards bodies of the following countries: Australia, Belgium, Brazil, China, France, India, Norway, Switzerland, United Kingdom, U.S.A., and U.S.S.R. The council appointed M. Henri St. Leger to be general secretary, and his office will be in Geneva.

Extension of Welfare Foods

Children at day nurseries are now, like those at nursery schools, to have two-thirds of a pint of liquid, or dried, milk daily free of charge. Each child is also to have one 6-oz. bottle of cod-liver oil compound every 12 weeks free of charge. From August 1 every mother will be entitled to vitamin A and D tablets free of charge for 30 weeks after the birth of her child at the rate of one packet each 6 weeks. The tablets will be distributed at the same centres as other welfare foods.

A new periodical, the *Chronicle of the World Health Organisation*, will regularly describe the activities of that body. The first number contains accounts of the origin, constitution, functions, and objectives of the organisation. Specimen copies may be had from the WHO interim commission, at the Palais des Nations, Geneva, or at 350, Fifth Avenue, New York, U.S.A.

CORRIGENDUM.—F. E. Adair's paper on the Use of Male Sex Hormone in Women with Breast Cancer appeared in *Surgery, Gynecology and Obstetrics* (1947, 84, 719) and not in the *Journal of the American Medical Association* as stated in our editorial (July 12, p. 61).

Births, Marriages, and Deaths

BIRTHS

ADKINS.—On July 6, the wife of Mr. E. W. O. Adkins, F.R.C.S.—a son.
AUGER.—On July 6, the wife of Dr. Harold Auger—a son.
BALL.—On July 5, in London, the wife of Major P. H. Ball, R.A.M.C.—a son and a daughter.
CARSTAIRS.—On July 12, at Okayama, Japan, the wife of Lieut.-Colonel L. S. Carstairs, R.A.M.C.—a son.
DODD.—On July 9, in London, the wife of Mr. Harold Dodd, F.R.C.S.—a son.
ELVERSON.—On July 4, at Marlborough, the wife of Captain H. J. Elverson, R.A.M.C.—a daughter.
GRIFFITHS.—On July 10, in London, the wife of Dr. A. J. M. Griffiths—a son.
HILL.—On July 4, at Stonehaven, the wife of Captain Adrian Hill, R.A.M.C.—a son.
HUDSON.—On July 5, in London, to Dr. Jessie Hudson, the wife of Dr. E. H. Hudson—a daughter.
LANGFORD.—On July 6, the wife of Dr. C. C. Langford—a son.
MACARTNEY.—On July 7, in Manchester, the wife of Dr. Donald Macartney—a son.
PERFECT.—On July 10, at Awali, Bahrein Islands, Persian Gulf, the wife of Dr. John Perfect—a son.
POCHIN.—On July 3, in London, the wife of Dr. E. E. Pochin—a daughter.
TETTMAR.—On June 28, at Westcliff-on-Sea, the wife of Dr. F. Tettmar—a son.
WHITING.—On July 4, in Boston, Mass., the wife of Dr. R. C. Whiting—a son.

MARRIAGES

BURROWES—WEST.—On July 5, at Bramshott, D. E. St. J. Burrowes, M.B., to Kathleen Ruth West.
BURTON—DE MARCHI.—On July 6, in London, L. J. H. Burton, M.R.C.S., to Isabella De Marchi.
LUSH—GEE.—At Hutton, Essex, on July 12, Brandon Lush, M.R.C.P., to Margaret Gee, M.R.C.S.
PATON—PEPYS.—On July 12, at Newbury, Alexander Paton, M.B., to Ann Jennifer Pepys.
SERGEL—STILEMAN.—On July 8, in London, Charles Sergel, M.B., to Elizabeth Joan Stileman.
SYKES—CUNNINGHAM.—On June 19, at Wolfenbüttel, Robin Sykes, B.M., captain R.A.M.C., to Jean Cunningham.

DEATHS

FLINT.—On July 9, at Surbiton, Harold Edwards Flint, M.R.C.S.
MANSIE.—On July 10, in London, James Mansie, M.B. Aberd.
NICHOLSON.—On July 9, at St. Leonards-on-Sea, Charles Rowley Nicholson, M.R.C.S., aged 74.
PETERSON.—On July 8, in London, Helen Peterson, M.D., D.P.M.

The deformity consequent on pneumonectomy is slight and only shown by some falling in of the chest wall and pulling over of the mediastinum. The general function is often excellent, depending on the state of the cardiovascular and respiratory systems, and may allow full normal activities short of strenuous exercise.

Local recurrence of the growth is a common cause of later death, the dead space becoming slowly filled with growth in 12–18 months. Distant metastases may develop at any time. Patients with only one lung are clearly liable to risks from respiratory infections, and with increasing years there is no doubt that the loss of pulmonary tissue throws an added strain on the cardiovascular system. Three patients unexpectedly committed suicide some time after operation, and in the absence of cerebral secondaries anoxia should be considered as a factor in any alteration of mentality that may be noted.

The results clearly leave much to be desired; but, as in all cases of malignancy, the uncertainty of the result cannot deter the surgeon from undertaking legitimate risks.

It should also be realised that in earlier years cases were operated on which would not now be regarded as operable. The selection has become more exact, technique has developed, and earlier diagnosis has paved the way for improved results.

BACTERIOLOGY OF THE COLLECTION AND PRESERVATION OF HUMAN MILK*

JOYCE WRIGHT
D.M. Oxfd
MEMBER OF THE MEDICAL RESEARCH COUNCIL'S SCIENTIFIC STAFF

PÆDIATRICIANS in general agree that newborn infants, particularly if premature, thrive best on human breast-milk; its wider provision is therefore important in the improved care of young babies. The suggestion was made that expressed breast-milk might be collected from maternity hospitals and preserved, possibly by dehydration, for distribution elsewhere.

The results presented here are those of an investigation of the bacteriology and of the safeguards required for ensuring an uncontaminated supply. Samples of human milk were obtained from three maternity hospitals in or near London (hospitals A, B, and C) and from a country maternity home (hospital D).

METHODS OF COLLECTING HUMAN MILK

Current methods of collecting human milk in maternity hospitals were first reviewed to find out whether any improvements in technique were required. Bacterial counts of milk samples were made by the roll-tube method (Wilson 1935). 'Yeastrel'-milk-agar was used as the medium, and the tubes were incubated aerobically for 3 days at 37°C.

Hospital A

As a routine, mothers emptied their breasts of excess milk after each breast-feed. Manual expression was usual, but some patients preferred to use a breast-pump. Collecting-bowls were washed between each use but were not boiled. Mothers' nipples and hands were not cleansed either before breast-feeding or before withdrawal of milk. Raw pooled milk was stored in a jug at room temperature and fed to infants as required.

Hospital B

Routine manual expression after each breast-feed was usual here also; breast-pumps were only exceptionally used. Milk, if for a mother's own infant, was collected in a boiled bowl and given raw. Milk for general infant feeding was expressed into unboiled bowls; it was then boiled and stored in a refrigerator until required.

Hospital C

Removal of excess milk after breast-feeding was the routine for all mothers, who withdrew it either by manual expression or by pumping. Collecting-bowls were boiled between each use. The breast-pumps were washed only between use, as they were of a type not readily sterilisable. The mothers' nipples and hands were cleansed before expression. Pooled milks were boiled and stored in a refrigerator until required for infant feeding.

Hospital D

Mothers' breasts were not emptied after feeding unless it was thought necessary on clinical grounds.

Table I shows, from roll-tube bacterial counts of milk collected in hospitals A and C, that high counts result when milk is collected by methods at present in use in some maternity hospitals. It is possible for these highly contaminated milks to be stored at room temperature and to be fed raw to premature and other newborn infants.

TABLE I—BACTERIAL COUNTS OF HUMAN-MILK SAMPLES COLLECTED BY METHODS CURRENT IN MATERNITY HOSPITALS

Hospital	Pooled or individual samples	Counts per ml.	Hospital	Pooled or individual samples	Counts per ml.
A	Pool	3,800,000	A	Ind.	600,000
A	,,	63,000	A	,,	2,500,000
A	,,	600,000	C	Pool	850,000
A	,,	3,600,000	C	,,	1,700,000
A	,,	8,000,000	C	,,	530,000
A	,,	5,000,000	C	,,	890,000
A	,,	3700	C	,,	3,000,000

MINIMAL BACTERIAL COUNT OF HUMAN MILK

Since the existing methods of collection were evidently unsatisfactory, work was next directed to establishing the lowest bacterial counts obtainable under the most favourable conditions—i.e., by direct spray into autoclaved bottles after the nipples had been cleansed with sterile cotton-wool, forceps, and water. The object was to establish an ideal standard against which could be measured bacterial counts obtained later by a practicable clean technique. Samples were placed in the refrigerator immediately after being taken and were prepared for counts within an hour of chilling.

Table II shows the bacterial counts of human-milk sprays collected in this way.

TABLE II—BACTERIAL COUNTS OF HUMAN-MILK SPRAYS COLLECTED FROM ONE BREAST ONLY IN EACH PATIENT

Case	Counts per ml.	Case	Counts per ml.
1	130	4	17
		,,	13
2	260	5	40
,,	260	,,	30
,,	45	,,	10
		6	2500
3	10	,,	850
,,	0		
,,	0	7	4500

In cases 2–6 the counts shown are for successive sprays from the same patient. In case 7 the sample contained numerous *Staph. aureus;* this patient had mastitis of the opposite breast.

SOURCES OF BACTERIAL CONTAMINATION

The bacterial counts given in table II show that the milk was exposed to heavy contamination during collection. Investigation was therefore directed to finding the major causes of the contamination.

---

* Following unpublished studies by Mr. Arnold Walker at the Willesdon and Perivale Maternity Hospitals, the Medical Research Council, at the request of the Ministry of Health, appointed a small committee, of which Mr. Walker was a member, to inquire into the conservation of human milk. Some of the work done for the committee is reported in this and a subsequent paper.

discovered on routine investigation or on mass radiography, and an abnormal shadow may be detected before any clinical signs have developed. The interpretation is not always straightforward, owing to secondary changes, in which case the picture is often that of the secondary change, and further investigation is necessary.

Blood.—Apart from routine clinical investigations, a careful hæmatological survey should be made. Anæmia may be present, and a raised sedimentation-rate is regularly found.

Bronchoscopy has to be performed as a routine if surgery is contemplated, since the growth may be seen and be available for biopsy. Pressure on the bronchi from growth or glands, and infiltration, deformity, or rigidity of the bronchi can be observed. Bronchoscopy, however, gives only a restricted view of the bronchial tree: the upper-lobe bronchi are visible only over a small length; but usually the information obtained is most valuable.

Bronchography can help in defining obstruction of bronchi beyond the range of the bronchoscope, but it is a subsidiary examination and should not take priority over bronchoscopy.

Sputum.—Investigation of the sputum for malignant cells has proved of great diagnostic importance. It is essentially an examination to be made by an expert and must not be undertaken within a fortnight of bronchoscopy or any manipulation which leads to desquamation of bronchial epithelium.

SURGICAL TREATMENT

The type of growth has considerable bearing on the duration of the disease and on the possibility of surgical removal. Oat-celled carcinomata with heavy regional metastasis are not suitable for excision, and few victims survive for any length of time. Squamous-celled tumours which produce early atelectasis are often localised and removable. A peripheral adenocarcinoma, which in our experience is uncommon, may be anatomically suitable for excision. The presence of secondary infection in the lung clearly adds to the hazards but does not preclude surgery.

It is generally admitted that the only hope of successful treatment lies in radical surgery. Radiotherapy has been disappointing in its long-term results, though sometimes it has been palliative. The possibilities of combined surgery and radiotherapy have not been fully explored.

Operation consists of dissection pneumonectomy, in which the lung and glands are excised after the individual elements of the hilum have been secured. Occasionally the excision may be confined to a lobe when the general condition does not permit of the more radical operation. The procedure was in the experimental stages ten years ago, but in the last six or seven years the work of the thoracic team has produced results which, as regards the actual operation, can be considered satisfactory. In our last 53 cases there was only 1 death due to operation. Certain types of case which used to be operated on are now excluded—e.g., pleural effusion, obvious glandular involvement, infiltration of the mediastinum and phrenic and vagus nerves, and extension into diaphragm and chest wall. These complications are not absolute contra-indications to operation, but they make its success doubtful.

The proportion of patients with pulmonary cancer suitable for radical surgery is depressingly low. Only a few are referred to the surgeon, and the figures of Brock (1943) and of Tudor Edwards (1946) show that only a few of these are operated on. Out of 224 patients Brock only found 40 suitable for consideration; out of the 36 treated, excision was only practicable in a half. In other words pneumonectomy was performed in 8% of the total. The current figure is, however, almost double this (Brock 1947). Tudor Edwards recorded 70 pneumonectomies and lobectomies out of 1016 patients seen.

In our series the chest was opened in 246 cases, and the growth excised in 130.

PNEUMONECTOMY: 122 cases

Within 1 yr.	3	1–2 yr.	1
1–3 yr.	2	2–3 yr.	1
		3–4 yr.	1
	5		3

THORACOTOMY: 116 cases (excision not practicable)

The limits of age at the time of operation were 28 and 71 years. Of the deaths between six weeks and two years after operation, 3 were occasioned by suicide, 3 from established coronary disease, 1 from accident, and 3 from incidental causes—i.e., 10 out of 47 in these groups died from causes unconnected with the original disease.

As a result of operation 19 patients died, 18 (15%) after pneumonectomy and 1 after lobectomy. These figures include deaths not only directly after operation but also up to six weeks after. The causes of early death included shock, hæmorrhage, heart-failure, and air embolism, but the chief danger lay in bronchial fistula and pleural infection. This complication, though not necessarily lethal, throws a considerable strain on the patient and causes protracted disability. Most of the patients who died from six weeks to six months after operation had developed metastases, some probably unrecognised at the time of operation, others from imperfect removal, or very rapid recurrence, of the tumour.

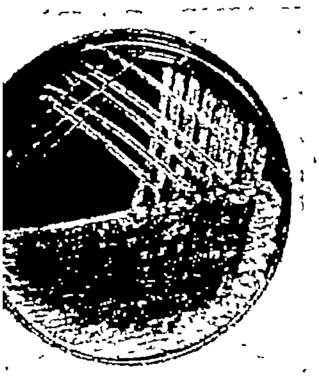
The technical problem of effective bronchial closure has been the biggest difficulty and, in spite of considerable recent improvements, has not yet been solved. Carefully placed sutures, penicillin, and pleural and intercostal muscle-grafts now maintain permanent closure in most cases. Penicillin has proved of inestimable value in controlling pleural infections.

The assessment for operation requires the most careful consideration. The respiratory and cardiovascular systems must be capable of withstanding the strain of a severe operation, and routine measurement of the vital capacity and pulse pressure should be made. Any deficiency in the hæmoglobin content should be restored by blood-transfusions before operation is undertaken. A preliminary pneumothorax may give information about the extent of pleural adhesions and, if it produces an efficient collapse, gives some idea of the ventilating capacity of the opposite lung.

The importance of having an experienced anæsthetist cannot be over-emphasised. Blood-transfusions are always given during the operation. The technique of pneumonectomy has been described on various occasions, and the methods used in this series showed no special variations. In 6 cases the pericardium was partially excised, and in 5 cases a wide section of chest wall was removed, to ensure adequate removal of the growth.

POSTOPERATIVE COURSE

The main feature in the postoperative course is the behaviour of the vacant space left after the pneumonectomy. In the absence of infection the space is slowly obliterated in a few months with an increasing deposit of fibrin over the walls. Pleural infection is often controlled with penicillin; but, if a large bronchial fistula develops, drainage will become necessary, with the result that closure is indefinitely delayed. Later a limited thoracoplasty may sometimes be used to obliterate the space.



l—Bacterial growth from unboiled collecting-bowl.

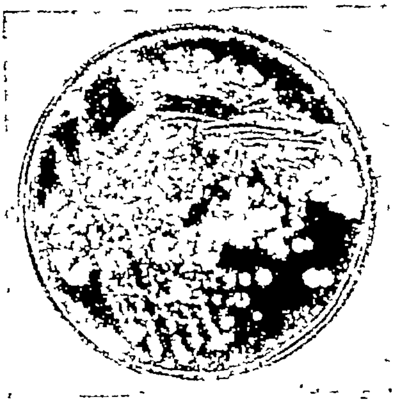


Fig. 2—Bacterial growth from unboiled breast-pump.

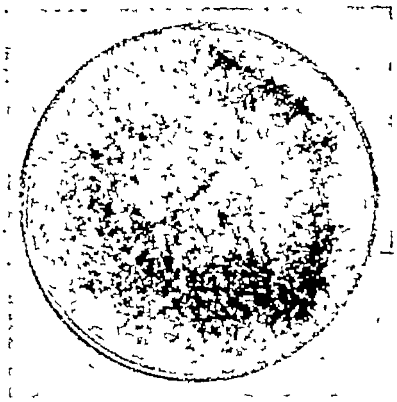

Fig. 3—Bacterial growth of human milk collected by clean technique.

h a few exceptions, the samples were taken by the n ward technique. Not all the samples came from rent mothers, as some mothers had their milk tested e than once. Aerobic cultures from 95 samples were le on blood-agar plates incubated at 37°C for 24–48 rs ; anaerobic cultures from 30 samples were made on d-agar plates and/or cooked-meat broth subcultured, r 48 hours' incubation, on to blood-agar plates. erobic plates were incubated at 37°C for 48–72 hours. results are shown in table III.

BLE III—BACTERIAL FLORA OF HUMAN-MILK SAMPLES

Bacterial flora	Aerobic culture	Anaerobic culture
rococcus :		
npigmented	73	24
ellow	11	5
olden	7	2
ph. aureus (coagulase-positive)	18	8
eptococcus :		
lpha-hæmolytic	20	10
on-hæmolytic	28	10
htheroid bacillus	8	4
obic spore-bearing bacillus	5	0
liform bacillus	0	2
isseria catarrhalis	0	1
vobacterium	1	0
nilia	1	0
rcina	2	1
ctobacillus	0	1
identified	1	0
Total no. of samples examined	95	30

icrococci

Thirty-one strains of micrococci from human milk were bjected to the tests (pigment formation, gelatin liquefaction, duction of nitrates, and utilisation of ammonium phosphate) ed by Hucker (1928) in his classification of the micro- cci. According to this scheme, 15 were *Micrococcus casei*, *M. candidus*, 4 *M. aurantiacus*, 1 *M. conglomeratus*, and *M. ureæ-freudenreichii*.

Lipolysis by micrococci may have a bearing on the splitting fats in raw human milk during storage. Thirty-three rains of micrococci were tested for their lipolytic activity growing them on 1% tributyrin-agar for 24 hours at 37°C. xcept one unpigmented strain, all showed a clear zone of olysis round their colonies. Twelve strains were grown on uman-cream-agar, and all, except one yellow strain, showed olytic action.

aph. aureus

Table III shows that, of 95 milk samples, 18 contained *Staph. urcus* (coagulase-positive), an incidence considerably lower than the 92% found by Duncan and Walker (1942), who collected their samples by expressing drops of milk on to sterile swabs, whereas in the present investigation the milk was collected in amounts rarely less than 20 ml. These larger volumes would ensure a thorough washing out of the nipple ducts ; further, staphylococci, if scanty, might be diluted to the point of absence in one loopful. When samples were collected by the method of Duncan and Walker, 8 out of 10 produced *Staph. aureus* (coagulase-positive). Six out of eight pooled samples of human milk collected by nurses using a clean ward technique produced this organism.

When considering the safety of pooled human milk collected by nurses in maternity wards, it would be safe to assume that a high percentage will contain coagulase-positive staphylococci ; it is unlikely that the comparatively low figure shown in table III would be maintained where milk is collected routinely every three to four hours.

Streptococci

Fifteen strains of alpha-hæmolytic streptococci were investigated. All were heat-sensitive (at 60°C for 30 min.) ; fermented glucose, lactose, sucrose, and maltose ; and produced acid, or acid and clot, in litmus milk. None of the strains grew at 45°C ; reduced methylene-blue in milk ; liquefied gelatin ; split æsculin ; hydrolysed sodium hippurate ; fermented inulin, mannite, sorbite, or xylose ; or grew mucoid colonies of *Strep. salivarius* (Niven et al. 1941) on sucrose-agar. Three strains fermented trehalose, five raffinose, and seven salicin. Six of the fifteen strains reacted with group-G serum (one cross-reacted with group-E serum), three reacted with group-H serum (two cross-reacted with group-D and group-K sera, and one with group-K only), and one reacted with group-D, group-H, and group-K sera ; the remaining five strains did not react with sera from group A to group M.

In the early stages of the work limited tests were made on twenty-one strains of streptococci. Eleven strains were non-hæmolytic on horse-blood agar ; four of these were heat-resistant and grew on MacConkey's medium, and two of the four fermented mannite. The remaining ten strains were alpha-hæmolytic. One of these was heat-resistant, grew on MacConkey's medium, and fermented mannite. The other nine were heat-resistant.

Coliform Bacilli

Seven strains of gram-negative coliform bacilli were investigated. Five of these were *Bact. alcaligenes* and two *Bact. aerogenes*.

Samples of human milk collected in a clean manner contained bacteria commonly found on the skin or in the upper respiratory tract and showed little evidence of fæcal contaminants. In samples collected into unboiled vessels, on the other hand, coliform bacilli (*Bact. coli*, *Bact. aerogenes*, and *Bact. alcaligenes*) were often numerous.

DISCUSSION

With the current methods of collecting human milk in maternity hospitals the danger of spreading infection between and among mothers, infants, and staff is too obvious to require elaboration. The risk of spread of

Collecting-bowls

The inner surfaces of six unboiled bowls in use in the wards were swabbed with dry or broth-moistened swabs. These were spread on blood-agar plates, which were incubated aerobically for 24 hours at 37°C. All six bowls examined in this way yielded a heavy bacterial growth. In two cases a "sweep" of the growth was examined microscopically and showed abundant gram-positive cocci and gram-negative coliform bacilli. Fig. 1 shows the growth on a plate spread with a swab dipped into the milk in an unboiled bowl standing ready for use in the ward.

Breast-pumps

In hospital A the Toronto breast-pump was used. This is a heat-resistant glass flask with curved neck and a side-arm for connexion by rubber tubing with a rubber bulb. Swabs of the inner surfaces of three unboiled pumps ready for use in the wards yielded a confluent foul-smelling growth when plated on blood-agar and incubated aerobically for 24 hours at 37°C (fig. 2).

One defect of the Toronto breast-pump is that, by suction and by gravity, milk is sucked back into the rubber bulb; bacteria multiply in the bulb and are forced back into the glass flask at its next use. Milk squeezed from the rubber connexion of a breast-pump on to a blood-agar plate produced numerous *non-hæmolytic streptococci and some micrococci.*

In hospital C a breast-pump fixed to its rubber bulb was used. It could not easily be sterilised and was therefore obviously unsuitable for use in maternity wards. Two samples of milk collected with this type of pump had bacterial counts of 1,730,000 and 2,960,000 per 1 ml.

Mothers' Hands

Fingers of ten mothers were swabbed immediately after manual expression; they yielded a heavy bacterial growth in seven instances and a scanty growth in three.

Nipples

One nipple of each of five mothers was swabbed before and after breast-feeding. The swabs were spread on blood-agar plates (incubated aerobically for 24 hours at 37°C), and a note was made of the amount of bacterial growth yielded by swabs taken before and after breast-feeding, and of any flora added to the nipple during the feed. Non-hæmolytic streptococci were apparently added during breast-feeding to four of the five nipples, and *Staph. aureus* (coagulase-positive) to two. In three instances bacterial growth from the nipple swabs was less after breast-feeding than before; in one it was heavier and in another unchanged.

Droplets

Since the mothers did not wear face-masks during manual expression, droplets emitted through talking or coughing over collecting-bowls were a possible source of milk contamination. Bacteriological observations were not considered necessary on this point.

Dust

Mothers were usually in bed when expressing their milk; hence dust contamination by blankets and garments could not be avoided. Milk after expression was further exposed to dust as it stood in the uncovered bowls awaiting collection by a nurse.

Towels and Face-cloths

During manual expression mothers were apt to use their towels and face-cloths for mopping milk from their breasts and hands. Soiled towels were therefore a possible source of contamination, as a liberal supply of clean towels was not available during the war.

A CLEAN AND PRACTICABLE METHOD OF COLLECTING MILK

The need for improvement in methods of collecting milk was obvious, and the following method, simple enough to be practised under conditions of shortage of staff and materials, was worked out by Sister E. M. C. Edwards.

Collecting-bowls

Bowls are boiled in the ward steriliser before each use. They are then stacked one in another until required for use, and a cover is placed over the top one.

Breast-pumps

The glass flasks and rubber connexions of the Toronto breast-pumps are boiled in the ward steriliser before each use.

Hands

Mothers are provided with bowls of water for washing their hands before breast-feeding and again before the withdrawal of milk. Nurses are instructed to wash their hands before touching a mother's breasts.

Nipples

A no-touch technique is used. Before mothers start breast-feeding, the nurse in attendance cleanses each mother's nipples and areolæ with sterile water and sterile cotton-wool held in boiled forceps. With her forceps she then places a piece of sterile gauze over each nipple. The gauze is held in place by the mother's brassière until she starts feeding from the breast. The whole procedure is repeated for each mother when she has finished feeding her baby and therefore before she starts expression or pumping.

Face-masks

Any mother with an infection of the upper respiratory tract wears an impermeable mask during breast-feeding and withdrawal of milk.

Towels and Face-cloths

Mothers are instructed to bring two towels into hospital with them. One is for general purposes, and the other is reserved for the breasts and hands during breast-feeding and withdrawal of milk. (Normally a liberal supply of clean towels would be provided by the hospital, but at the time of the investigation this was impossible.) The use of face-cloths during the withdrawal of milk is not permitted.

Heat Treatment

All the milk is brought to the boil immediately after collection.

Twelve milk samples collected in hospitals A and B into boiled bowls (without hand or nipple cleansing) had bacterial counts ranging from 120 to 100,000 (mean 13,330) per 1 ml. This striking reduction from the high counts, running into millions per ml., when unboiled bowls were used indicated that the main source of milk contamination lay in dirty vessels.

Similar reductions in bacterial counts resulted from the boiling of breast-pumps. Seven samples of milk collected in unboiled pumps had counts ranging from 530,000 to 3,000,000 (mean 1,440,000) per 1 ml., whereas six samples from boiled pumps had counts ranging from 1000 to 24,000 (mean 10,700) per 1 ml.

Of thirty milk samples collected by the clean technique described above—i.e., including hand washing and nipple cleansing—bacterial counts ranged from 70 to 39,000 (mean 8600) per 1 ml. Fig. 3 shows a typical blood-agar plate spread with a loopful of raw milk collected by the clean ward technique and incubated aerobically for twenty-four hours at 37°C.

HEAT TREATMENT OF HUMAN MILK

Three methods of heat treatment of human milk were tested—holder pasteurisation at 63–65°C for 30 min.; high-temperature flash pasteurisation at 80°C; and boiling.

Holder pasteurisation reduced the bacterial counts of thirty-four milk samples, ranging from 70 to 37,000 (mean 9200) per 1 ml., by 99·9%. The seven surviving bacteria were four aerobic spore-bearing bacilli and three unpigmented micrococci. The method is impracticable for ward use, because a heat-controlled water-bath is required for holding milk at the correct temperature.

High-temperature pasteurisation in a saucepan, with a guarded thermometer, gave less satisfactory reductions of bacterial counts than did the holder method.

After pasteurisation by either method, rapid cooling of the milk is required; without special equipment this is impracticable in wards. An added difficulty in ward pasteurisation is that the procedure of heating, cooling, and bottling milk, when repeated five or six times daily, takes too much of the ward sister's time.

Bringing the milk to the boil in a lidded saucepan is the most satisfactory method of heat treatment of milk in wards. A thermometer is not required, and, owing to the almost complete sterility of the milk, slow cooling can safely be allowed.

BACTERIAL FLORA OF HUMAN MILK

The bacterial flora of 85 individual and 10 pooled samples of milk from hospitals A and B were investigated.

denly at a time when the patient felt himself to be victim of grave injustice. In each case there was a scious attitude of "ability" or "having deserved l." As soon as the facts were elicited, a discussion ued in which the relationship between the skin dition and the past emotion was indicated.

At first I attempted to achieve all this in one interw. The effect, however, was rarely satisfactory. st patients became uneasy and took the discussion lly. Some ultimately did well, but most never came k. In the latter cases, where the consequences became own to me, I discovered that my precipitate probing d provoked an aggravation of the skin lesion. It came apparent therefore that, in bringing back to e patient's conscious mind half-forgotten wrongs, his otions relating to past injustice were kindled afresh, d that an alarming exacerbation of dermatitis was ble to follow. Premature discussion clearly not only ded to the patient's discomfort but was likely to terrupt treatment.

Case 2.—A male school-teacher, aged 60, had dermatitis the left leg below the knee. Five years earlier an eruption d appeared in the lumbar region and rapidly spread over e trunk and limbs. The axillæ and scrotal regions had been fected most severely. There had been redness, oozing, aling, and intolerable itching. He had been confined to d for months, and for nine months had not been able to llow his employment.

Since the onset he had never been quite free from the erupon; at no time had there been a smaller area involved than hen I first saw him. He blamed a woollen belt for his condion. However, he had worn this and similar belts for many ears previously because of "lumbago." He had been tended by many doctors, chiefly dermatologists.

Life Situation.—His wife and four children were all in good ealth. For over thirty years he had been teaching in a wellnown school, and he had been very keen to obtain a headastership; but invariably his application for the coveted ost had been passed over, simply because (he said) his subject as science and not classics, English, or mathematics. It is a ule with the education authority that no application for eadmastership is likely to be entertained if the applicant s over 55 years of age. During the month before his reaching he critical age two headmasterships had become vacant, but gain he had been disappointed. The eruption had appeared few days after his birthday and rapidly covered him from the rown of his head to the soles of his feet.

Treatment.—At his first interview the elicitation of the above tory was followed by a full discussion. But the first interview was also the last—he did not come back. I learnt that within few days of the interview the dermatitis had become almost s widespread and severe as it was at its worst five years earlier.

Further experience showed that the mere outpouring of the essential features of a life story in relation to the onset of dermatitis might exacerbate the condition, even when care was taken not to discuss their significance. As successful treatment depends on the capacity of the patient to face his past tragedy and yet no longer to feel under a sense of injustice, the problem is by no means easy. Success in treatment requires as a preliminary the establishment of a good transference during the first one or two consultations by making a most complete general physical examination coupled with a careful inquiry into all symptoms of any kind. Then the life situation before the onset may be discussed, and, at the next sitting, the relationship between emotion and skin. Finally, if possible, a solution of some practical kind must be put forward for discussion.

Case 3.—A factory manager, aged 44, had had dermatitis herpetiformis for two years. The eruption was well marked, especially over the trunk, showing the typical appearances of erythema, vesicles, bullæ (many of them dry, like a two-weekold vaccination scab), and scaling.

Six years earlier he had had itching of the skin; this had become worse in the next four years, but an eruption had not appeared until two years ago. The hands and arms had been first affected, but soon the whole body had been covered. Six months after the onset of the rash his doctor had referred him to a dermatologist, whom he had attended until now. The appearance of the eruption was much as it had been eighteen months ago.

Life Situation.—He had entered his present employment many years ago as manager. Some years later he had married the owner's daughter. The administration of the business had been carried out jointly by the owner and the manager in perfect harmony. The owner had led him to believe that, on his retirement, the patient would have an opportunity of buying the business for £10,000. But the owner, just when about to retire, had died suddenly, a little over six years ago. His son (patient's brother-in-law), who had not hitherto been associated with the business, had decided to take over control. He knew little or nothing about running the business, and the administration had remained in the hands of the patient. However, the new owner had given him no credit for any successful transactions but had invariably found fault with him over trifles.

Two years ago the patient had discovered that the business was being advertised for sale. When he had reminded the owner that he had been promised an opportunity of buying at an advantageous figure he had been laughed at. The business had been sold to an outsider about eighteen months ago for £20,000, a sum considerably in excess of what the patient could raise or believed it to be worth. He had been retained in his previous position of manager but with less authority and with a smaller salary.

Treatment.—I began with a searching physical examination, including scrutiny of the skin, examination of heart, lungs, blood-pressure, reflexes, urine, and sedimentation-rate. At the second consultation his symptoms were noted in great detail. For example, which parts of his body itched most? At what time of day did he suffer greatest discomfort? Did climate or diet affect him? Other symptoms, such as his tendency to nasal catarrh, were studied no less meticulously. These consultations established confidence. At the third consultation the patient felt better, and his skin had notably improved. On this occasion his life situation was elicited, and he confessed to a keen sense of being treated badly ever since the late owner of the business had died six years ago (itching appeared soon after this), and that his sense of injustice had reached a climax two years ago.

Three days later I was called to his home, where he presented a pitiable picture. He was covered with vesicles and complained bitterly of itching and burning. I explained that such a relapse was to be expected as a result of *recall* of disturbing emotional experiences—just as the primary onset of the skin trouble had been provoked by the actual experience. He saw the point and accepted the logical conclusion not only that his present exacerbation was the result of his emotions being stirred but also that cure would follow his ability to escape from the sense of injustice which had burdened him these last six years.

With this realisation he now began to improve; and, when he revisited my consulting-room a month later, there were no fresh vesicles, and he was almost free from itch. He had decided to find employment elsewhere. A month later he told me he had obtained another post and was now entirely free from itch and eruption. I saw him again a year later, when he said he was applying for and hoped to obtain a still better post, that he had had no recurrence of skin disorder, and that he felt better than he had done for years.

EFFECTS OF PHYSICAL IRRITATION

Many of us find that certain areas of skin, notably the backs of the hands, crack and even bleed during a spell of cold frosty weather. However, it is also common experience to find that after a few mild days the skin has regained its normal texture without any treatment whatsoever. The removal of the environmental cause of the disorder is sufficient to bring about cure. It seems curious that, when a patient complains of a skin disorder, accepted as being due to a physical irritant, such as cracks behind the ears which he attributes to the metal frame of his spectacles, the eruption may fail to clear when he ceases to wear the offending glasses, and may spread over large areas of skin.

Case 4.—A theatre manager, aged 40, complained of four weeks' irritation, followed by cracks, behind both ears. The cracks looked like streptococcal fissures. He attributed the cutaneous lesion to his metal spectacle frames but admitted epidemic neonatal diarrhœa owing to laxity in handling milk was emphasised by Sakula (1943); some of the infants affected in his ward were fed on additional bottle feeds of human milk. Since mastitis is not uncommon among nursing mothers, the possibility of staphylococci being carried from one mother's breast to another's by unboiled collecting-bowls and breast-pumps must be borne in mind. Storing raw milk at room temperature for infant feeds is a dangerous practice; *Staph. aureus*, some strains of which produce enterotoxin, is prevalent in maternity hospitals and may unwittingly be contributed in large numbers to a human-milk pool by a donor with unrecognised mastitis. Growth of staphylococci, if allowed to occur, may produce a "toxic" milk for infants fed by bottle.

It is recommended that maternity hospitals should overhaul their methods of collecting human milk and pay particular attention to the boiling of all collecting-vessels; breast-pumps which cannot readily be sterilised should be replaced by more hygienic types, human milk should be boiled *immediately* after collection, and refrigerators should be supplied for its storage.

SUMMARY

Human milk collected by methods current in maternity hospitals had bacterial counts ranging from 3700 to more than 8,000,000 (mean, more than 2,230,000) per 1 ml. In some wards pooled raw human milk was stored at room temperature and used without heat treatment for infant feeding.

Human milk collected with strict precautions by direct spray into autoclaved bottles had bacterial counts ranging from 0 to 2500 (mean 298) per 1 ml.

Contamination of human milk was mainly due to unboiled collecting-bowls and breast-pumps. The introduction of boiled collecting-vessels, without other precautions, reduced the mean bacterial count by 99·3%.

A clean and practicable method of collecting human milk in maternity units is described. Bacterial counts of thirty milk samples collected in this way ranged from 70 to 39,000 (mean 8600) per 1 ml.

Heat treatment of human milk by holder and by high-temperature flash pasteurisation was tested. A reduction of the mean bacterial count by 99·9% was effected in thirty-four milk samples pasteurised by the holder method. High-temperature flash pasteurisation (80°C) was less effective in reducing the bacterial count. Both methods were considered impracticable for routine ward use, mainly owing to the difficulty of correct temperature regulation and of rapid cooling. Bringing the milk to the boil was considered the quickest and safest method of heat treatment in wards. Emphasis is laid on the importance of heat treatment of milk *immediately* after collection.

Micrococci were the bacteria most commonly found in human-milk samples collected in a clean manner, followed closely by non-hæmolytic and alpha-hæmolytic streptococci. *Staph. aureus* (coagulase-positive) was found in 18 of 95 samples examined. Milk collected in unboiled vessels often contained coliform bacilli (*Bact. coli*, *Bact. aerogenes*, and *Bact. alcaligenes*).

My thanks are due to the members of the committee for their interest and encouragement; to Prof. A. A. Miles for laboratory facilities at University College Hospital Medical School, London, and for his advice; to Dr. A. T. R. Mattick and Dr. P. M. F. Shattock for temporary laboratory facilities and valuable suggestions; and to the doctors and nurses of the hospitals concerned.

EMOTIONAL ASPECTS OF SKIN DISEASE

G. GLADSTONE ROBERTSON
M.D. Glasg.

Halliday[1] in 1944 noted a common factor in the emotional life of a series of middle-aged men who, for the first time, had suddenly contracted widespread dermatitis which was particularly resistant to treatment. The patients were upright good-living men keenly conscious of their own virtue and rectitude; the onset of the skin eruption followed closely some disaster; and the patients felt that their misfortunes were undeserved, that other men less righteous had escaped such a catastrophe, and they laboured under an acute sense of injustice. Halliday recalled an observation made thousands of years ago and labelled the condition "Job's dermatitis."

This association of ideas—Job and dermatitis—was brought to memory when I encountered the following case.

Case 1.—A Jewish storekeeper, aged 66, had had extensive "eczema" for three years. Almost the whole of his skin had been involved at one time or another. The onset had been sudden, and the dermatitis had spread rapidly, accompanied by intolerable itching. In the first year he had consulted his family doctor and three or four dermatologists. In the past two years he had attended weekly at an outpatient department.

Life Situation.—He was living alone in a single apartment. Twenty-five years ago, at the age of 41, he had married a beautiful girl aged 17, an orphan without dowry. Five months after the marriage she had given birth to a daughter—not his child. He had forgiven her and brought the child up as his own. He had lavished kindness and money on both wife and daughter.

He had been successful in business and owned two retail shops besides having an interest in a wholesale establishment. Except for a few hundred pounds, he had placed all his assets, including his business, in his wife's name. Five years ago, when he was 61, she, then aged 37, had formed an attachment with another man, dispossessed her husband of his entire fortune, and sacked him from his own business. Litigation had followed and dragged on for two years. His capital had been exhausted, which had prevented him from contesting the matter further. At this point his skin eruption had made its first appearance.

As he related his story, he repeatedly emphasised his goodness to his wife and the rectitude of his past life. He seemed also to link his past business and material success with his righteous way of living.

Treatment.—In the course of discussion I said to him, "You will no doubt have heard of Job?" He replied, "Doctor, I was born and brought up in Russia. I knew the book of Job almost by heart before I was 14 years old." I said, "Then you will remember that he was the most prosperous man in the land, and that he regarded his great wealth as no more than a just reward for his righteousness? And you will remember how thieves and robbers stole his flocks and herds and burned his crops, and how a whirlwind destroyed his seven sons and three daughters. You will remember also how his soul was torn in pieces. It was beyond his comprehension how such disaster could befall a man so good as he, who believed the tally of his riches was the measure of his righteousness. You will remember what happened to him. His body itched and oozed intolerably. So has yours."

He was greatly moved and said nothing for a few minutes. Then with tears in his eyes he informed me that I was the first person to give him some inkling into the real nature of his trouble.

After this initial interview there was a severe exacerbation of the dermatitis, followed by gradual improvement, until six weeks later the skin became normal. There has been no recurrence, though he has complained of itch from time to time.

INITIAL EXACERBATION AS RESPONSE TO PSYCHOLOGICAL APPROACH

During the next few years I saw several patients in middle or late life in whom dermatitis had appeared sions draws one to the conclusion that, when a patient obsessed with a sense of injustice, resentment, and lf-pity, changes in the skin sometimes take place. A ime comes when irritants, such as flannel binders, pectacle frames, oil, flour, sugar, or a new fur, may ppear to be the last straw to break the camel's back. Iow partial is the importance of these things in the tiology of the dermatitis is shown by the fact that the emoval of the alleged irritant is not followed by melioration of the dermatitis. Indeed one surmises that, no irritant had been applied, the skin would soon have rupted spontaneously.

---

[1] Halliday, J. L *Practitioner*, 1944, **152**, 6.

In treating such cases it would of course be a mistake o suppose that the patient is ill because he tried to be l, or that a desire to be better will rid him of the illness. he doctor will do him no good by adopting an aggressive ttitude, by displaying exasperation, or by employing uggestion. The technique of treatment should be amed at extirpating "a sense of injustice" from the atient's emotional life.

SUMMARY

Patients with intractable dermatitis may sometimes e found to labour under a deep sense of grievance. nquiry into the emotional difficulties associated with the nset of the dermatitis may cause an acute exacerbation. On the other hand, when these difficulties are resolved r even when the patient is given insight into them, he dermatitis may rapidly clear.

Often industrial dermatitis cannot be satisfactorily xplained by the action of the irritant substances to which the skin is exposed. The underlying cause may be n emotional disturbance.

EFFECT OF MASS OF INOCULUM ON VIRULENCE OF BACTERIA

INJECTED INTRAPERITONEALLY IN MICE

J. M. BARNES
M.B. Camb.

From the Microbiological Research Department, Experimental Station, Porton

THE induction of infection by the intraperitoneal oute in mice is a common laboratory practice. I wish o draw attention to a technical point in it that may be ignificant in the comparison of results obtained by lifferent workers using the same strain of a pathogenic rganism. No claim is made for the originality of these bservations.

Albino mice weighing 18–20 g. were used, and all injections vere made with 1 ml. tuberculin-type syringes. For the nthrax experiments, diluted samples of a stock concentrated pore suspension fully lysed were used. In every experiment sample of the material injected into the mice was counted y the method of Miles et al.[1] The infected mice were housed ingly or in pairs in small metal boxes, and deaths were ecorded daily. A blood-smear was prepared from all dead nimals.

For the experiments with the staphylococci, a strain pathogenic to mice was obtained from Dr. M. A. Jennings, of Oxford. The mice were infected with 18-hour cultures in ryptic meat-broth or with suspensions in distilled water repared from growths on tryptic meat-agar and standardised n the Brown opacity scale.

EXPERIMENTS AND RESULTS

A series of mice were infected by the intraperitoneal njection of the same number of anthrax spores suspended n different volumes of distilled water. The results table I) show that the death-rates among the groups f mice receiving the same numbers of spores rose as the olume of the inoculum was increased from 0·1 ml. per mouse to 1 ml. The same experiments were repeated with the anthrax spores suspended in saline (0·85% sodium chloride) instead of distilled water. The results (table II) show that with saline an increase of the mass of the inoculum was without significant effect in raising the mortality.

TABLE I—EFFECT ON MORTALITY AMONG MICE OF INCREASING VOLUME OF DISTILLED WATER IN WHICH A GIVEN NUMBER OF ANTHRAX SPORES ARE INJECTED INTRAPERITONEALLY

Volume of distilled water (ml.)	Average no. of spores per dose					
	30		300		3000	
	No. tested	Mortality (%)	No. tested	Mortality (%)	No. tested	Mortality (%)
0·1	30	*21*	30	*53*	30	*90*
0·25	40	*30*	40	*77*	10	*100*
0·5	110	*72*	110	*97*	100	*100*
1·0	30	*90*	10	*90*	..	..

In a preliminary attempt to investigate the mechanism of this action of distilled water, groups of mice were infected with anthrax spores suspended in 0·1 ml. of distilled water. At different intervals before and after receiving the spores, the mice were given an intraperitoneal injection of 1 ml. of distilled water. The results (table III) show that the death-rate among mice receiving the additional 1 ml. of water is only increased above those receiving the 0·1 ml. of spore suspension alone when the distilled water is administered within two hours either before or after the injection of the spores. The lower death-rate among mice receiving the distilled water twenty-four hours before the spores may be the result of some mild non-specific irritation enhancing the local tissue defences. Further studies of the mode of action of the distilled water have not been undertaken.

TABLE II—FAILURE TO INCREASE MORTALITY AMONG MICE RECEIVING SAME NUMBER OF ANTHRAX SPORES BY INJECTING SPORES IN GREATER VOLUMES OF NORMAL SALINE

Volume of saline (ml.)	Average no. of spores per dose					
	30		300		3000	
	No tested	Mortality (%)	No. tested	Mortality (%)	No tested	Mortality (%)
0·1	30	*16*	30	*50*	30	*97*

[1] Miles, A. A., Misra, S. S., Irwin, J. O. *J. Hyg., Camb.* 1938, 38, 732.

that these had been worn by him for over ten years without previous trouble.

On my advice he temporarily discarded the spectacles. Ointments containing antiseptics, chiefly sulphathiazole, were applied. The fissures healed but soon reappeared and now seemed resistant to these and various other local remedies. A few weeks later dermatitis appeared on the back of the neck and the face.

Life Situation.—He had married twelve years ago. Before marriage his wife had been a dancing instructress. She had an extreme mother-attachment, and he said that even yet he felt that her mother meant much more to her than he did. Like most such women she was sexually frigid. Her only pregnancy, ten years ago, was terminated because of hyperemesis gravidarum—as might be expected.[2]

He did not usually leave the theatre at night until *10.45*, reaching home about *11.15*. It was his custom to telephone his wife when some untoward happening made it possible for him to come home earlier. About five months before the onset of his illness he went home one night at 9.30 without making the usual telephone call. On going upstairs he found a man, unknown to him, in his wife's bedroom with her. There was no definite evidence of misconduct, but he became obsessed with doubts and suspicions.

He was an uncompromising type of man, with a limited capacity for seeing another's point of view. He adhered to his own principles and standards, judging others by them; nor, having once formed an opinion, did he readily change his mind. Since the bedroom episode his wife and he met only at meal-times and rarely exchanged a word. He maintained a cheerful exterior to his business associates but ruminated unceasingly on his domestic crisis. Providence had been unkind to him. For many years he had endured a wife who was not in love with him and who had now perhaps added infidelity to her failings.

Progress.—Though I knew this man personally and the transference was good, in a day or two he became covered from head to toe with a papulovesicular eruption. After further discussion he agreed that his skin disease was determined by his recent emotions, and that the present state of affairs should be terminated, either by reconciliation with his wife or by a complete break. He took a month's sick leave, which he spent in his native town. After a week he came to a decision and instigated proceedings for a divorce. By the end of his month's holiday he was free from dermatitis. No treatment other than psychological investigation and discussion was used. During the next four months, pending legal hearing and judgment, he had repeated crops of boils, but this affection also came to an end when he was granted a divorce. He has now resumed wearing his spectacles and has remained trouble-free for many months.

INDUSTRIAL DERMATITIS

During the war years there was an increase in the incidence of so-called industrial dermatitis. The vast majority of the cases occurred among munitions-workers, and the oils used in the engineering industry have been blamed for them. Yet it is extraordinary that a person should be able to work with oil for months or even years without discomfort and then should develop dermatitis, which is rarely limited to the parts of the skin which came into contact with the oil. Moreover, if the oil was the sole ætiological factor in the production of the dermatitis, one would expect that withdrawal from the noxious agent would be rapidly followed by spontaneous cure, or at least by obvious improvement. But this never happens. On the contrary, the dermatitis, is liable to drag on for months, to spread all over the body, and to resist external medicaments. During this period the patient becomes anxious about his earning ability, and, besides drawing his weekly compensation, often consults a solicitor with a view to obtaining a capital sum to reimburse him for the damage inflicted on his skin, "because, as everyone knows, the dermatitis may return at a later date."

Case 5.—A male munitions-worker, aged 33, had four months' dermatitis affecting arms, hands, trunk, and legs. He had been attended by one of my assistants for three months, but on his own request was referred to the outpatient dermatological department of a hospital a month ago.

He had been employed for $2^1/_2$ years in an aero-engine factory. There was no previous history of dermatitis. The eruption, at first consisting chiefly of dry red papules but later tending to become vesicular and to weep, appeared originally on the backs of the hands and forearms. He was at once taken from work, but the disease spread all over his body, improving here and becoming worse there. The general severity had remained unchanged over the past three months.

Life Situation.—He had been married ten years and had three children. He was a skilled engineer and ambitious to "get on." His wife and he were well educated, but owing to his small salary had to live in a two-apartment flat, with an outside lavatory, in a poor part of the city. At the time of marriage their names had been placed on the corporation waiting-list for a new house; but, though new houses had been granted to others, they were still waiting.

At the outbreak of war he had been switched to aircraft engines. He had accepted his present job with fairly good grace, though it entailed longer travelling to and fro, night-shifts, and long hours of work, until six months ago, when he found that other men in certain factories were earning much more than he, with less travelling, shorter hours, and no night-shift. When he sought transfer to one of these factories nearer his home, he came up against the Essential Work Order.

Progress.—He admitted that his feelings of being unjustly baulked and frustrated at every turn reached an extreme pitch four or five months ago. When I indicated that his dermatitis appeared precisely at that point of time, and inferred that his emotional state might have been a causal factor, he resented intensely the implication that there was anything psychological about his condition and asserted that he was determined to obtain his rights at last by making the factory pay handsomely for what he was suffering. Next day he complained to my assistant that I was trying to swindle him out of his just and lawful compensation. His heightened sense of injustice was accompanied by such an exacerbation of the dermatitis that my assistant removed him forthwith to the local hospital. However, his wife came to see me later and assured me that a more discontented man than her husband never lived, and that she believed my interpretation of his illness to be correct.

After a few weeks he was discharged from hospital, but the skin condition dragged on for months much as it had been in the earlier stages. Eventually he received a sum of money in compensation. This was followed by steady improvement. Soon afterwards the authorities permitted him to enter the factory of his choice. Within a week the last vestige of dermatitis disappeared. He has continued to work there for the past eighteen months and has kept completely free from skin eruption though, I believe, the composition of the oil used in this factory differs in no way from the oil used by his previous employers.

Case 6.—A single woman contracted erysipelas of the face three times, had a crop of boils, and finally was affected with dermatitis involving the trunk and inner thighs. The hypersensitivity of her skin began after a junior worker was promoted over her head to the position of forewoman.

Case 7.—A single woman, working in a tobacco factory, contracted dermatitis of the hands. She had worked with tobacco for five years without trouble. Her forewoman had taken a fancy to her and asked her to accompany her to dances and places of entertainment in the evenings. She disliked the forewoman and stalled the invitations. When the forewoman grasped the situation she made the girl's life a misery. Unpleasant jobs were given her, and fault was found with everything she did. When later she was transferred to another department (in the same factory and handling tobacco as before) the skin cleared in a few days.

Case 8.—A man cut his leg accidentally in a shipyard. The cut showed no sign of healing. Dermatitis appeared round the wound and commenced spreading up the leg. He had been taken from his own work and sent to a shipyard two months ago. He could see no reason for the change other than the tendency of the labour exchange to delight in expressing authority by forcing round pegs (and good hickory pegs too) into square holes. Incapacity continued for some months, but wound and dermatitis healed in a very short time when it was made known to him that pressure had been brought to bear on the directors of labour, and that he was to return to his old peace-time job.

A survey of the life situation and underlying emotions of patients afflicted with dermatitis and many other skin

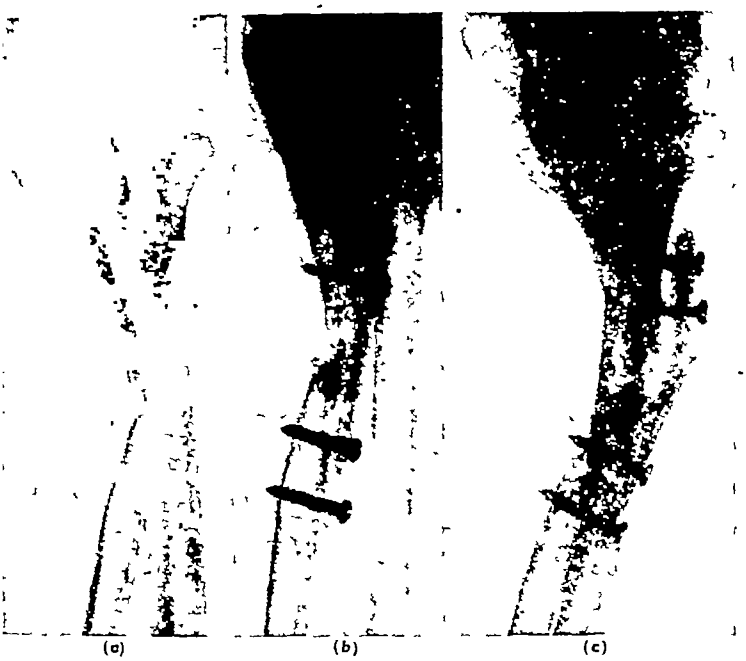

Fig. 1 (case 3)—(a) On admission 2 years after fracture. (b) After onlay grafting. (c) 3 months later: the graft has been applied under a strain and has fractured.

ntroduction of dead material into the wound) further equestrectomies may become necessary, greatly prolonging the time of disability. Grafting with cortical bone should never be done unless the dangers of introducing infection can be avoided. With old compound fractures, previously infected, penicillin makes operation safe at an earlier date than would have been considered before its use, but even with penicillin at least three months must elapse, after sinuses have healed, before grafting should be done. Failure will always result if there is dead bone at a fracture site, even if the sinus has been long healed. The presence of a sequestrum contra-indicates grafting.

Grafting under Strain

Bone-grafts do not survive a serious bending strain. This fact is more important in some situations than in others, and success depends on the surgeon's realising the danger and so planning his operation as to avoid a strain passing across the graft. This can be done by placing the graft on the correct aspect of the bone, by added protection externally, and if necessary by the use of a bone plate as well as the graft. The most notable example of this particular difficulty is the upper shaft of the ulna. The liability to angulation in fractures in this situation is well known. The ulna usually bows towards the radius, the radius and the lower ulnar fragment falling inwards. Unless the graft is properly placed, or the fracture plated also, the graft will gradually fade away under the strain, angulation will increase, and non-union will persist.

Nutrition of the Graft

This will depend both on the sort of bone that is used for the graft and on the bed in which it lies. We have not found that the removal of periosteum from the graft or the presence or absence of muscles overlying the graft has any appreciable effect. It is of course important that grossly sclerosed bone is not used, and in some tibial fractures a graft from the opposite leg may be more valuable than the usual sliding type. More importance attaches to the bed in which the graft lies. If the graft crosses a gap, or an area of avascular fibrous tissue or sclerosed bone, its revascularisation will be delayed or prevented, and the operation may fail.

The most useful adjunct to cortical grafting in these cases is the use of cancellous bone chips. The chips should be used to fill the cavity beneath the graft after the removal of poorly nourished scar and bone. They may be inserted at a previous operation or at the same time as the cortical grafting.

It should be remembered that the general condition of the patient may affect the nutrition of the graft, the speed of union, and the success of the operation. Case 6 (see below) illustrates this. Age seems to have little effect, but prolonged illness, and such diseases as syphilis, cause delay in the union of fractures whether after grafting or not.

Immobilisation

This must be considered both in fixation of the graft and of the ends of the fractured bone. Success ultimately

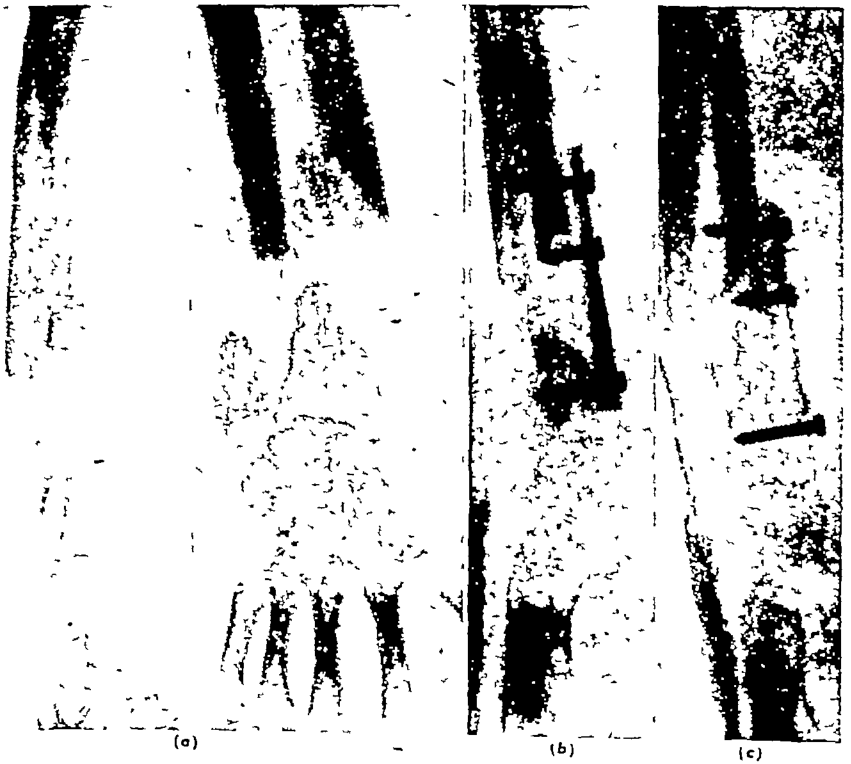

Fig. 2 (case 5)—(a) On admission. (b) After onlay grafting. (c) 4 months later: the nutrition of the graft is inadequate and the graft is fading away.

TABLE IV—EFFECT OF VOLUME OF NUTRIENT BROTH ON DEATH-RATE AMONG MICE INJECTED INTRAPERITONEALLY WITH 18-HOUR CULTURES OF *Staph. aureus*

Culture fluid injected (ml.)	No. tested	No. dying
Undiluted 1·0	74	72 (97·3%)
" 0·1	90	4 (4·5%)
Diluted 1 : 10 1·0	70	59 (84·3%)

A smaller group of experiments were carried out with a strain of *Staph. aureus* pathogenic to mice. The number of organisms needed to kill the mice when injected in 0·1 ml. of distilled water was about 1×10^{10}. The strain was not, therefore, very virulent.

Table IV shows that the virulence of a given number of organisms can be greatly increased by injecting them in 1 ml. of broth rather than in 0·1 ml. of broth. A similar effect was observed by varying the amount of distilled water in which a given number of cocci were injected (table V).

TABLE V—EFFECT ON VIRULENCE OF ADDING DISTILLED WATER TO SUSPENSIONS OF *Staph. aureus* INJECTED INTRAPERITONEALLY INTO MICE

Suspension injected (ml.)	No. tested	No. dying
Opacity 40 (Brown scale) 0·1 ..	14	11 (78·5%)
" 4 " " 0·1 ..	30	1 (3·3%)
ditto plus 1 ml. water ..	24	17 (70·8%)

CONCLUSION

The virulence of a particular organism used for the intraperitoneal infection of mice should be expressed in terms of the mass of the inoculum besides the number of viable organisms. The effect on the activity of antibiotics by the enhancement of virulence as a result of increasing the mass of the inoculum seems to be worthy of attention.

I wish to thank Dr. D. W. Henderson, chief superintendent, Microbiological Research Department, Porton, for his help and advice, and the Chief Scientist, Ministry of Supply, for permission to publish.

FOLIC ACID IN MEGALOBLASTIC ANÆMIA AFTER TOTAL GASTRECTOMY

REPORT OF A CASE

M. E. MORGANS
M.B. Lond., M.R.C.P.

C. RIMINGTON
M.A., Ph.D. Camb., B.Sc. Lond.

N. WHITTAKER
M.D. Camb., M.R.C.P.

From the Medical Unit and the Department of Pathological Chemistry, University College Hospital Medical School, London

FOLIC acid has been shown to be effective in the treatment of pernicious anæmia, nutritional macrocytic anæmias, and the megaloblastic anæmias associated with sprue. The response of megaloblastic anæmia following gastrectomy to folic acid treatment has been described in America,[1] but the cases are so rare, and the data on them of such theoretical importance, that it may be of interest to record a further case.

A commercial artist, aged 42, was admitted to University College Hospital on July 19, 1946, with three months' history of lassitude. In July, 1943, his stomach had been resected from 3 in. above the cardia to the second part of the duodenum by Prof. R. Pilcher for lymphosarcoma. His diet had been adequate in all respects.

On examination patient was a little pale but not icteric. Tongue and nails normal. Spleen not palpable. Abdomen showed a midline supra-umbilical scar. No evidence of recurrence of tumour. Central nervous system showed evidence of subacute combined degeneration of the cord of peripheral neuritis.

Blood: Hb 72%, red cells 3,280,000 per c.mm., cell diameter 8·3 μ, mean cell volume 100·6 c.μ, mean puscular Hb concentration 30·1%; reticulocytes 0·5%, cells 4500 per c.mm. (polymorphs 70%, lymphocytes monocytes 2%).

Bone-marrow megaloblastic (July 12, 1946).

Van den Bergh reaction showed an indirect positive, 0·8 bilirubin per 100 ml.

Fractional test-meal showed a histamine-fast achlorhydria.

Stools: six specimens examined for occult blood negative.

Radiography: no evidence of secondary deposits in skeleton and barium meal showed no recurrence of lymphosarcoma.

No detectable porphyrins in blood and urine.

Treatment and Progress.—A course of folic acid 10 m intramuscularly every 24 hours was begun on July 23. There had been no reticulocyte crisis on the eighth day when the dosage of folic acid was doubled, and the reticulocyte count rose to 4·2% and thereafter subsided.

On August 6 blood examination showed Hb 90%, red cells *3,500,000* per *c.mm.*, mean *cell diameter 8·2 μ*, mean c volume 100 c.μ, mean corpuscular Hb concentration 33 At this time (the fourteenth day) the marrow was wholly normoblastic. At this stage folic acid was discontinued and patient then received 'Hepolon' 4 c.cm. on alternate days.

On discharge from hospital on August 26 his Hb was 90%, red cells 4,260,000 per c.mm., mean cell diameter 8·0 μ, mean cell volume 100 c.μ, mean corpuscular Hb concentration 29%.

Though there was not a large reticulocyte response in this case, the replacement of a definitely megaloblastic by a normoblastic marrow when folic acid was exhibited shows the drug to have been hæmopoietically effective.

We wish to thank the Lederle Laboratories Ltd. for their generous supply of folic acid through Cyanamide Products Ltd.

FAILURES IN CORTICAL BONE-GRAFTING

V. H. ELLIS
B.Chir. Camb., F.R.C.S.

H. H. LANGSTON
M.B. Lond., F.R.C.S.

J. S. ELLIS
M.Chir. Camb., F.R.C.S.

FORMERLY SURGEONS TO AN E.M.S. ORTHOPÆDIC CENTRE

BONE-GRAFTING with cortical bone is done in fractures of the shafts of the long bones for three main reasons: (1) for non-union; (2) as part of the reduction and fixation of fractures that are uniting or have united in an unacceptable position; and (3) to expedite delayed union. With these indications we operated on 94 out of *1085 fractures of the shafts of the long bones:*

Bone	*No. of shaft fractures*	*No. of grafts*
Humerus	130	13
Radius and ulna	187	23
Femur	266	12
Tibia	502	46
Total	1085	94

CAUSES OF FAILURE

Whatever type of cortical graft is used—inlay, onlay, sliding, or intramedullary—the same five factors are of chief importance in influencing failure: (1) sepsis; *(2) application of the graft under strain; (3) inadequate* nutrition of the graft; (4) lack of immobilisation of graft and/or fracture; (5) lack of protection before union is solid.

Sepsis

If a grafting operation is followed by sepsis of bone not only is its success endangered but also (by the

It is therefore necessary for any laboratory under-king serious Rh-testing to have available a panel of nors, preferably among the laboratory staff, whose N, P, and, if possible, Lutheran and Willis types are own besides their ABO and Rh types, and for any usual agglutinin to be tested against a much larger nel of cells representing various combinations of ctors than the conventional Rh_1, Rh_2, and rhrh cells.

Only three previous examples of anti-N agglutinins ve been recorded, one of which, a naturally occurring ti-N agglutinin, was noted by the late G. L. Taylor ut not published. Taylor's observation was recorded Callender and Race[1]; the other two, described by nger[2] and by Callender and Race,[1] are regarded as mune anti-N agglutinins produced in M-patients by ansfusions with N-containing blood. The evidence for allender and Race's agglutinin being an immune one incontrovertible, but from the published data it seems st possible that that of Singer may have been a aturally occurring one.

CASE-RECORD

A married woman was referred to us by Mr. Arnold Walker r investigation because of two unexplained miscarriages, ach at about 5½ months' gestation. She had never had a ansfusion.

The patient's cells belonged to group A and were Rh-positive. hen her serum was tested for agglutinins, the sediment attern on removal from the incubator was regarded as egative.

When, however, after standing on the bench for some time and so attaining room temperature, which often was as low s 14°C) the sediments were examined microscopically, ery powerful clumping was seen with the Rh_1Rh_1 and rhrh ontrol cells, but none with the Rh_2 cells.

From the general appearance we thought it unlikely that his was a Rh-agglutinin, though on theoretical grounds it ould have been anti-e or anti-d, if certain assumptions were ade about the true genotypes of our control cells.

However, when the patient's serum was tested against a panel of group-O and group-A bloods, agglutination took place with all cells of types N and MN but not with type M, irrespective of ABO, Rh, or P groups.

It was therefore clear that we were dealing with an anti-N agglutinin, and this was confirmed by Dr. R. R. Race on a further panel of donors of known MN group.

The patient's husband, who belonged to group A, was Rh-negative and M, so there seems no doubt that this agglutinin is a natural and not an immune agglutinin; further, the agglutinin-titre has remained constant.

Properties of Agglutinin.—The optimal temperature for the agglutinin was room temperature (14–19°C). There was no agglutination at 37°C, and results were obscured by a non-specific cold agglutinin at 2°C. Even at this low temperature, however, agglutination of N and MN cells was much more powerful than that of M.

The temperature effects were reversible: an incubated sample gradually developed clumping as the temperature fell, and the non-specific 2°C agglutinins disappeared on warming to room temperature, giving quite clear N readings.

The thermal amplitude of his agglutinin is not mentioned by Singer, but we are informed by Dr. Race that his anti-N serum also works best at room temperature.

Characters of Agglutination.—The clumps of cells formed at room temperature were very large and firm and were not broken up on tapping the tube; they resembled much more the ABO type of agglutination than the Rh type.

The agglutinin titre, determined by mixing neat or diluted serum with an equal volume of 2% red-cell suspension and allowing the mixture to stand on the bench at room temperature for at least two hours, was 1/8 on three separate samples.

The result with the 1/2 dilution was absolutely massive clumping, much more like an ABO effect than the Rh type, but at 1/8 there were small clumps with many unagglutinated cells. (The figures indicate the actual final dilution: *not* the dilution of serum before the cell suspension is added.)

Sediment Pattern.—As mentioned above, when agglutination was carried out at 37°C, the sediment pattern was negative. At room and lower temperatures there was a tendency to a "positive" type of pattern, though generally not so clear as in a good Rh agglutination. If the cells were allowed to settle, and then shaken up and allowed to resediment, a clear sediment pattern was usually obtained.

Since these agglutinins show little action at 37°C, it seems questionable whether they are likely to cause any serious troubles during transfusion. It is possible that, if cold blood were transfused quickly, there might be some clumping in the recipient's circulation, and, in fact, Singer's patient had a reaction. With a slow transfusion or warmed blood it seems unlikely that harm could result. On the other hand, it is clear from Callender and Race's work that repeated immunisation with N-containing blood can cause the development of powerful immune antibodies in some persons, and any transfusions in such a patient should be observed very carefully.

SUMMARY

Several abnormal agglutinins acting at low temperatures, including one anti-N and three anti-P agglutinins, have been met with. These are regarded as of natural, rather than immune, origin.

Though the agglutinins did not act at 37°C, agglutination took place in tubes which had been incubated at 37°C and subsequently allowed to stand on the bench before microscopical examination.

It is necessary to be on guard against such atypical agglutinins when testing for Rh antibodies. Any laboratory undertaking serious Rh-testing must have a panel of available donors whose MN and P characters are known besides their ABO and Rh groups.

Our thanks are due to Mr. Arnold Walker for allowing us to investigate the case with anti-N agglutinins, and to Dr. R. R. Race for confirming the anti-N and one of the anti-P sera and for his coöperation in many other problems.

HEPATIC DYSFUNCTION IN PEPTIC ULCER

OBSERVATIONS WITH THE HIPPURIC-ACID TEST*

H. POLLAK
M.D. Prague

With the technical assistance of C. E. INMAN, F.I.M.L.T.

From the Dietetic Department, Central Middlesex County Hospital

THERE are few studies demonstrating hepatic dysfunction in patients with peptic ulcer.

Pathological evidence of liver damage in peptic ulcer in man seems to have been first mentioned by Gandy (1899, 1910) and was demonstrated by biopsy by Vilardell and Corachán (1932), but this was only partly confirmed by the work of Schnitker and Hass (1934). Reviewing the large necropsy material of the Philadelphia General Hospital, Gordon and Manning (1941) noted again, apparently independently, a high incidence of hepatic lesions in ulcer patients. Boles et al. (1939) observed the association of hepatic lesions with acute ulceration.

Clinical evidence of hepatic dysfunction in ulcer patients is scanty.

Kalk (1931) noticed, in about a third of all cases of duodenal ulcer, various symptoms suggesting an involvement of the liver, such as enlargement and tenderness, a tendency to a raised serum-bilirubin, decreased bilirubin tolerance (Eilbott-Bergmann test), and an increase of urobilinogen in the urine. These changes tended to subside under strict treatment. A raised serum-bilirubin has been found in 10% of duodenal-ulcer patients by Johnson and Bockus (1943).

Jegersen and Simonds (1934) reported an increase in an enzyme (lipase), capable of splitting olive oil, in the blood of 38 out of 50 patients with peptic ulcer. This, in their opinion, points to a disturbance of function of liver or pancreas or both.

Sjöström (1937), who, in an extensive study, found the citric-acid content of the blood-serum to be a sensitive gauge of liver function, observed a moderate hypercitræmia in a large proportion of patients with peptic ulcer. This was

2. Singer, E. *Med. J. Aust.* 1943, ii, 29.

* Paper read at the annual meeting of the European Association of Clinical Pathologists, London, Nov. 27, 1945.

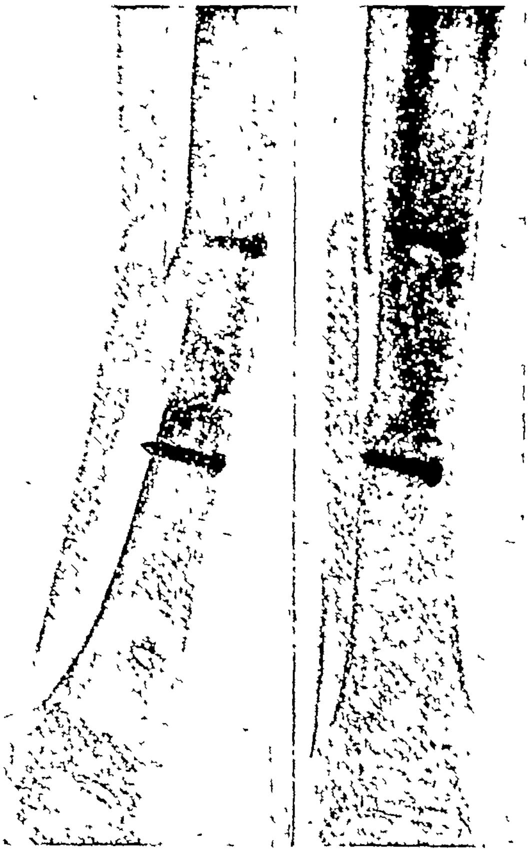

Fig. 3 (case 6)—A year after inlay sliding graft. The graft has become well incorporated, but there is practically no union of the fracture.

depends on the union of the fracture and not of the graft. The fixation of the fracture is much more difficult when the position has been changed at operation. When grafting is done in a fracture that is slow in uniting, but in which the position is adequate, the fibrous union is usually firm enough to prevent undue movement, provided external fixation is adequate.

Protection

Protection of the grafted fracture must continue until the graft has been revascularised. This period of protection is necessarily much longer when a gap has been filled. It will vary with the amount of strain thrown on the bone, and will of course be much longer in a weight-bearing bone. The other important factor is the leverage associated with a neighbouring stiff joint.

In this series 94 cortical grafts on long bones have been done, and there have been 8 failures. By "failure" we mean that we have failed to ensure union at the first attempt, and a further operation has been necessary. Success is due to a product of judgment and technique, and we think our failures have been due to errors of judgment rather than of technique. Our 8 failures occurred through offences against one or more of the five principles stated above.

ANALYSIS OF FAILURES

Case 1.—Male, aged 25. Compound fracture of tibia and fibula. Non-union 3 years. Cross leg skin flap from opposite calf. Sliding inlay bone-graft with 'Vitallium' screw fixation. Done too soon after skin-graft. Wound broke down. Bone sepsis. Failure. Regrafted. (Principle 1 transgressed.)

Case 2.—Male, aged 29. Gunshot wound; compound fracture of tibia and fibula. Ununited in poor position at 6 months. Sliding inlay. Few small sequestra found, though wounds had been healed at least 3 months. Wound broke down. Bone sepsis. (Principle 1 transgressed.)

Case 3.—Male, aged 20. Compound fracture of upper shaft of ulna, with dislocation of head of radius. Reduced. A with non-union and angulation 2 years after fracture (fig. Screwed onlay graft, and position corrected. Gradual " away" of graft. Angulation. Non-union. (Principle 2 gressed: this graft should have been accompanied by a plate

Case 4.—Male, aged 30. Compound fracture of lower tibia and fibula, with fracture of femoral shaft in same leg. Ununited at 7 months. Sliding inlay. Lower fragment was poorly nourished bone. Union not sound 8 months later. Regrafted. (Principle 3 transgressed.)

Case 5.—Male, aged 21. Compound fracture of lower of radius and ulna, with 2-in. gaps (fig. 2). Radius grafted without preliminary filling of bed with chips. Graft faded away. (Principle 3 transgressed.)

Case 6.—Male, aged 26. Simple comminuted fracture of middle of lower shafts of tibia and fibula. Reduced late in good position. Hæmatemesis from gastric ulcer at 3 months. Fracture ununited at 5 months. Sliding inlay graft. Partial gastrectomy for ulcer 6 weeks later. Uneventful convalescence. Fracture still ununited 1 year after grafting (fig. 3). (Failure of nutrition of graft from general causes.)

Case 7.—Male, aged 22. Compound fracture of mid-shaft of humerus. Had been distracted. Ununited in poor position at 4 months. Position corrected and inlay graft. Inefficiently immobilised in poor spica. Angulation at fracture. Graft shifted position. Ununited 5 months later. Regrafted. (Principle 4 transgressed.)

Case 8.—Male, aged 27. Gunshot wound; compound fracture of upper $^1/_4$ of tibia. Inlay sliding graft for non-union at 6 months. Clinically and radiologically united 4 months later; 6 months after grafting patient stumbled and put all his weight on the grafted leg. Refracture. (The knee movements were limited in this case and protection of some sort should have been further prolonged. Principle 5 transgressed.)

ANTI-N AND OTHER LOW-TEMPERATURE AGGLUTININS IN HUMAN SERUM

E. N. Allott

GROUP PATHOLOGIST

C. A. Holman
M.B. Lond.
ASSISTANT PATHOLOGIST

GROUP LABORATORY, LEWISHAM HOSPITAL

From the L.C.C. Pathological Service

During the recent winter an unusual agglutinin, subsequently found to be anti-N, was encountered in routine tests for anti-Rh agglutinins; its properties are described below.

Several other unusual agglutinins, which acted on some control cells but not on others, and resembled the anti-N in being more active at temperatures lower than 37°C, were later met with: three sera containing agglutinins with the specificity anti-P; and several others whose specificity was not related to ABO, MN, P, or Rh groups.

All these sera gave apparently negative "sediment patterns"; but, when the sediments were examined microscopically, agglutination was found to have occurred with some test cells, in some cases very powerfully. The phenomenon was due to the cells having attained the low temperature of the laboratory, often as low as 14°C, before microscopical examination. Probably the increase of routine Rh-testing will show that these agglutinins are less rare than has been supposed, and it is necessary to beware lest they be mistaken for immune anti-Rh agglutinins.

One of the anti-P agglutinins was definitely misleading at first. The test Rh_1Rh_1 and Rh_2 cells both showed microscopically powerful agglutination, though the sediment patterns were negative; the Rh-negative control cells were unaffected. When, however, the serum was tested against a larger panel of cells, only the P-cells were agglutinated, the pp-cells being unaffected, entirely irrespective of Rh type; purely by chance on this occasion both Rh-positive control cells were also P-positive, and the Rh-negative was pp-.

the values indicated occurred in normals; in the lower portion is shown the same for the ulcer group. On a statistical basis the results falling below three times the standard deviation from the mean in the normal group are significantly abnormal. There is an obvious tendency for the ulcer patients to have a lower output of hippuric acid as compared with the control group, though the impairment in function was, on the whole, moderate. The age is of importance, though it does not explain the difference in function between normals and patients. In the normal group there is little difference between the younger and the higher age-groups, but it is noteworthy that the reduction in output of hippuric acid is much more marked in the older patients. Some patients, and among those were a few with intractable ulcers, showed persistently low figures, but in most who were serially studied the output of hippuric acid tended to increase with improvement in general condition (fig. 3). This took place within a few days in some cases, while in others it took weeks. An impairment in function may therefore be easily missed when the test is done *some time after admission, if the patient has already* begun to improve clinically. The results with the intravenous modification (Quick 1939), though for various reasons not strictly comparable, showed changes in the same direction. It can also be seen from serial tests that a figure which appears but slightly subnormal as judged by the "normal range" may be considerably below the subject's maximum function. The reduction output of hippuric acid was, on the whole, greater in tients whose general condition was poor.

DISCUSSION

Though the possible *dissociation of functions* of the ver necessarily limit conclusions drawn from a single st, comparative studies with various current tests by ateer et al. (1942) and others have demonstrated the alue of the hippuric-acid test as an index of the functional pacity of the liver. Our data indicate a tendency to epressed liver function in a selected group of peptic-lcer patients, the impairment in function being greater the active phase of the disease.

There are three ways in which this disturbance may be lated to peptic ulcer:

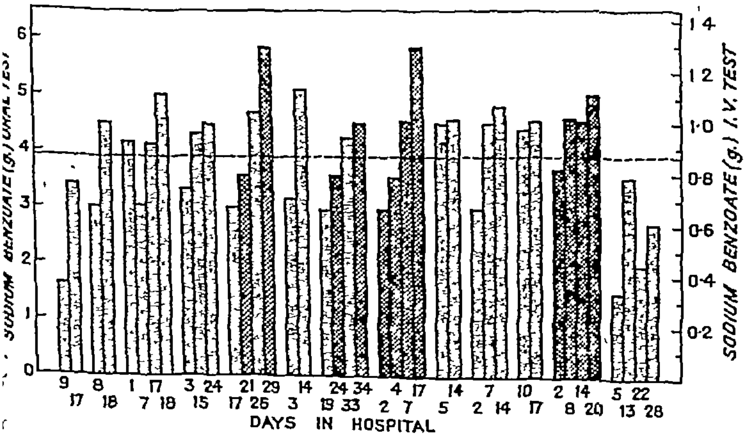
(1) *Hepatic dysfunction may be secondary to the gastric sion and its sequelæ.*—It is possible that pain, or disturbances the stomach and duodenum associated with or responsible or it, may reflexly create disturbances in the liver and iliary tract, as suggested by a correlation between pain and yperbilirubinæmia observed in duodenal ulcer (Kalk 1931). uch a possibility is further exemplified by the observation hat upper intestinal distension may depress liver function (Schnedorf and Orr 1942, Mann 1943). The possible effect of reduced food intake through pain, loss of appetite, and fear of eating appears to be a more obvious factor. The impairment in liver function, however, could not be explained in all cases solely by reduced food intake, though this may have been a contributory factor in many cases.

(2) *Both hepatic dysfunction and ulcer may be related to common factors.*—This includes the possibility of a metabolic inferiority as part of the "ulcer diathesis."

(3) *Hepatic dysfunction may affect the resistance of the gastroduodenal mucosa.*—There is much evidence suggesting that damage to the liver favours ulceration. Many types of liver injury (Eck fistula, ligation of the common bile-duct, bile fistula, hepatic toxins) are followed in a high proportion of instances by ulceration of the duodenum or of the stomach (Ivy et al. 1932, Schnitker and Hass 1934); and Crandall and Ivy (1938) have pointed out that most of the methods used experimentally to produce peptic ulcer seemed to depend on interference with hepatic function. As supporting evidence in human pathology, a high incidence of peptic ulcer in hepatic disorder, particularly hepatic cirrhosis, has been mentioned (Schnitker and Hass 1934, Ask-Upmark 1940a and b).

The idea of such a relationship does not necessarily imply hepatic dysfunction as a primary cause of ulceration in most peptic-ulcer cases, but it may be considered as a conditioning mechanism, particularly in relation to nutritional factors. One of the possible ways of explaining the connexion between hepatic damage and ulcer would be to assume an interference with the metabolism of dietary factors essential to the protection of the gastroduodenal mucosa (Ask-Upmark 1940b). Theoretically, most known dietary factors might be considered in this respect, particular emphasis having been laid on the rôle of protein (see Riggs et al. 1941) and various vitamins. Cheney (1942) has shown that ulcers produced with cinchophen in chickens may be prevented or modified by a new fat-soluble dietary factor (anti-gizzard-erosion factor, "vitamin U"), a lack of this factor in the diet producing similar lesions. Ask-Upmark (1940b) further considers the possibility of an intrinsic factor, stored and managed by the liver, being the "ulcer-protecting substance."

Apart from the possibility of such a causal relationship between hepatic dysfunction and ulcer through "conditioned deficiencies," the existence of metabolic disturbances possibly arising from hepatic dysfunction is of interest here as complementary evidence. Mackie et al. (1940) and Thiele and Scherff (1939) found in the blood of ulcer patients subnormal levels of vitamin A which were not explained by inadequate diet but might be due to reduced capacity of the liver to store vitamin A (Moore 1937) or to mobilise it normally. In view of this and the known association of liver disease and hemeralopia (Baas 1894, Feldman 1937, Patek and Haig 1939) it was not unexpected to find in our patients a tendency to impaired dark-adaptation which, as already noted by Stewart (1941), could not in many cases be explained by dietary vitamin-A deficiency but in the absence of evidence of malabsorption was explained by hepatic dysfunction (Pollak 1943). Both dark-adaptation and excretion of hippuric acid seemed particularly poor in patients with a "hepatic" complexion, and patients of this type were to some extent selected for study. Though there was in this group of patients an obvious tendency for both of these functions to be outside the range found in the normals, there was no strict correlation between them. The impairment in dark-adaptation, though more evident in the active phases of disease, did not depend on the presence of an ulcer, and possibly



ig. 3—Serial hippuric-acid tests on inpatients on standard ulcer régime. Stippled columns denote oral tests, cross-hatched columns intravenous. The broken horizontal line marks approximately the lower limit of normal.

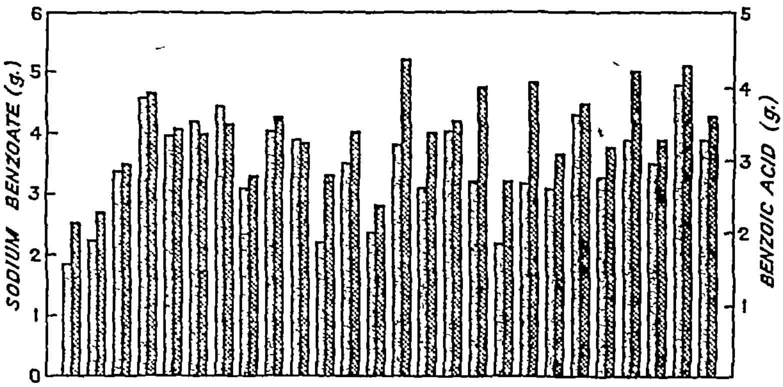


Fig. 1—Comparison of results of Quick's method and Probstein and Londe's method of determination of hippuric acid in the urine in 26 tests in normal subjects and patients. (Cross-hatched columns, Probstein and Londe's method ; stippled columns, Quick's method.)

attributed to a disturbance in liver function. A similar tendency was found also in patients with negative X-ray evidence but with a history suggesting ulcer dyspepsia.

Ask-Upmark (1940a and b), studying 28 cases (8 of gastric ulcer, 12 of duodenal ulcer, 3 of "pseudo-ulcer," and 5 post-operative), often found a pathological galactosuria (Bauer's test), and also a hypergalactosæmia after oral administration of galactose in 4 out of 7 cases. This and a hypercitræmia (in 7 out of 22 cases) were attributed to a functional impairment of the liver. The possibility that a rapid emptying of the stomach might alone be responsible for the excessive galactosuria was considered unlikely, since abrupt introduction of galactose into the duodenum of normal subjects did not produce a pathological galactosuria. This was observed also in ulcer cases without acceleration of the emptying of the stomach.

A pathological galactosæmia after oral administration of galactose has been independently observed by Meranze et al. (1942), who, however, leave open the question to what extent this may be due to increased intestinal absorption or liver dysfunction.

Morrison (1942) found "accidentally" that of 50 patients with peptic ulcer 36 had liver dysfunction ; this was tested by determining quantitatively (stalagmometrically) the bile-salt concentration in non-surgical biliary drainage, which is considered a most sensitive index of liver function.

Marino and Saladino (1937) noted an increase in certain *polypeptides in the serum in gastric and duodenal ulcer.* They put it down to functional disturbances of liver and kidney.

METHOD AND STANDARD OF NORMALITY

The analytical method of Weichselbaum and Probstein (1939) was used, following in detail the instructions given by Londe and Probstein (1941), except that an excess of concentrated hydrochloric acid was found an advantage (Kraus and Dulkin 1941). Weichselbaum and Probstein found that the addition of 30% of NaCl to the urine appreciably decreased and stabilised the solubility of hippuric acid, as was confirmed by Hepler and Gurley (1942) and others who used ammonium sulphate. The dose of the oral test was 6 g. of sodium benzoate, and the hippuric acid excreted was estimated in a pooled four-hour specimen of urine, the results being expressed in terms of sodium benzoate (see Pollak 1947).

Our "normal" figures with this method were higher than those given by Quick and others using his original precipitation method but agree closely with those reported by Probstein and Londe (1940) and Hepler and Gurley (1942). This is probably due in the first place to the improvement in the analytical technique and secondly to the selection of normals. *Fig. 1 shows a direct comparison* of the two methods carried out in 26 tests from aliquot parts of urine ; in half the tests the difference was more than 10%, the increase in the yield of hippuric acid by the NaCl modification being up to about 33%. Similar results were reported by Hepler and Gurley (1942). This in itself will appreciably reduce the standard deviation of a "normal" sample. It must be emphasised that our normal figures and those found by the above-mentioned investigators were obtained from perfectly healthy subjects.

There is evidence that many different illnesses, such as acute and chronic infections—pneumonia, rheumatic fever, endocarditis, and arthritis—low-grade illness due to chronic infection (Stiles et al. 1942), allergic conditions (Shay et al. 1939), pernicious anæmia, peptic ulcer, and surgical operations may be associated with hepatic dysfunction. A survey of the literature reveals that this has not always been *taken into* account in the selection of "normal" controls, who were often recruited from hospital patients "with no signs of obvious liver disease" but often with one of the above-mentioned conditions. Though this may have been justifiable, if not desirable, in the early work intended to demonstrate that the test was "positive" in liver disease, for the detection of subclinical impairment of liver function a stricter standard of normality was chosen. Our normal controls were subjects in perfect health, and special care was taken not to include those with, or giving a history of, any of the above-named conditions or dyspepsia. The observations in normals were also extended to a higher age-group, since liver function tends to deteriorate in old age (Rafsky and Newman 1943). Further, the two sex-groups were treated separately, since we found appreciably lower figures in healthy female subjects.

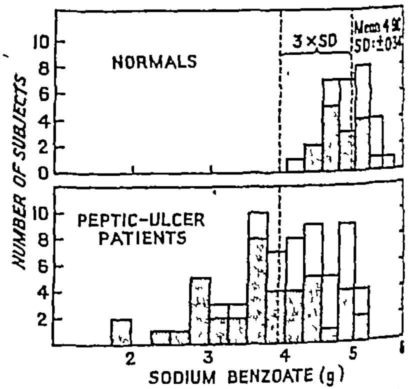

Fig. 2—Comparison of results of oral hippuric acid test in 67 male peptic-ulcer patients and 30 normal males. Stippled areas denote men aged 45-60, plain areas denote controls.

OBSERVATIONS IN ULCER PATIENTS

The following observations were carried out between May, 1941, and October, 1943, on inpatients. The subjects do not represent a random sample of ulcer patients. Patients with severe symptoms tend to be admitted to hospital for treatment, and those with a long history and severe symptoms resistant to treatment or those whose general condition was poor were preferred for study. Most came from a poorer social and economic level. 68 male patients, aged between 26 and 60, with uncomplicated gastric and/or duodenal ulcer were studied. The diagnosis was established by radiography and/or gastroscopy. The renal factor was controlled by blood-urea estimation (Londe and Probstein 1941), and the emptying-rate of the stomach was checked by the result of the standard fractional test-meal (Ryle 1926).

The existence of hepatic dysfunction in this selected group can be shown in two ways : *(1) by comparing* the results of the test in the ulcer patients with those obtained from the normal group ; and (2) by following up individual patients with serial tests during the course of the illness. Fig. 2 shows the comparative results with the oral hippuric-acid tests in the two groups. In the upper portion is shown the frequency with which eck were tense and prominent, making the neck look it. Movement of the neck appeared to be painful, though nderness was not severe; there was no true head-traction.

On lumbar puncture only two or three drops of clear fluid ere obtained, in spite of jugular compression. Aspiration ith a syringe, however, yielded 5 c.cm. of slightly blood-ained cerebrospinal fluid, which showed 1 6% protein, with "great increase" of globulin, 5000 red cells and 25 white ells per c.mm.

A course of sulphamezathine (0·25 g. four-hourly for five ays) was started, which appeared to have some good effect n the fever. After the first week he began to gain weight, nd the arms steadily improved in power and tone until three eeks after admission they appeared to be normal. The eck also assumed a more normal appearance.

A month after admission a lump suddenly appeared in the udline of the back of the neck. It became larger and uctuant. Aspiration produced thick greenish pus, which ontained very large numbers of *Staph. aureus*; 5 c.cm. of us was aspirated, and penicillin 15,000 units in 1 c.cm. f water was injected into the abscess cavity through the ame needle.

The swelling was aspirated twice in the next three days, enicillin being injected on each occasion. On the last spiration the fluid was brown and clear; after this the lump isappeared. A general course of penicillin was given for days, starting from the first aspiration—17,000 units ee-hourly for forty-eight hours, then reduced to 3000 ts four-hourly, a total of 440,000 units being given (locally l generally). The baby was kept for three weeks longer der observation but was to all intents and purposes a rmal baby, and gained weight.

Radiography.—Within a few hours of the baby's readmission liography revealed some erosion of the left transverse process C.4. A week later this was much more definite, and a lateral w showed erosion of most of the neural arches of C.3 and C.4, th fusion by means of thin bone of part of the laminæ, dicles, and spines of C.3, C.4, and C.5. Radiography a ek after discharge showed these three vertebræ fused egularly, rather bunched together, and fully recalcified. ere was never any evidence of a sequestrum.

DISCUSSION

The inflammation of the bone probably started in the ft neural arch or pedicle of C.4, as this appeared to be e centre of the decalcification.

The infective organism appears to have been derived om the paronychia, as these are nearly always due to aphylococci; if so 64,000 units of penicillin did not terilise this focus.

It is common for osteomyelitis to follow focal infection lsewhere. Thus, in Green and Shannon's series, 55% f the cases were preceded by boils, paronychia, chest fections, &c.

The paralysis of the arms was probably due to pressure n the cervical nerve-roots by granulation tissue and dema, rather than by pressure on the cord, since ecovery was so rapid and the legs were so little affected. levertheless there was a complete "spinal block" for erebrospinal fluid.

Osteomyelitis in infants differs from the osteomyelitis f older children and adults in the following particulars:—

(1) *Strep. hæmolyticus* occurs nearly twice as often s *Staph. aureus* in the lesions of infants, whereas nine-enths of the cases of osteomyelitis in adults are due to *taph. aureus*. This is probably due to the fact that the receding infection in infants is often a lung infection, hich is usually of streptococcal origin.

(2) The infection shows less tendency to spread widely, ften "coming to a head" and forming an abscess, hich works into the soft tissues spontaneously. There little necrosis of bone; it is rarely possible to demon-trate a sequestrum, and if one forms it is usually bsorbed spontaneously. The bone is more easily bsorbed and more quickly replaced by new bone; thus absorption of bone is radiographically demonstrable much sooner than in adults, and healing takes place rapidly. This is probably because infantile bone is porous, the cortex thin, and the periosteum loosely attached, compared with adult bone. Thus the abscess is not kept walled in under high tension and can work to the surface.

(3) The disease very rarely becomes chronic, and deformities are usually quickly rectified by growth.

(4) The treatment recommended is very different from the treatment of adult osteomyelitis. More attention must be paid to the general state of the infant than to the diseased part. With rest and splinting the infection will usually be localised. In many cases an abscess forms under the skin, which may be relieved by minor surgery or aspiration through a wide-bore needle. It may well be that a general course of penicillin would avert the necessity for major surgery much more effectively than in osteomyelitis in adults. If an abscess forms, the combination of local and general penicillin should lead to cure, since there is usually no dead bone to harbour the organisms, and if some dead bone is present it is usually quickly absorbed.

Reviews of Books

Studies of the Renal Circulation

JOSEP TRUETA, M.D., Hon. D.SC. Oxfd, ALFRED E. BARCLAY, D.M., F.R.C.P., F.F.R.; KENNETH J. FRANKLIN, D.M., F.R.C.P.; PETER M. DANIEL, M.B.; MARJORIE M. L PRICHARD, M.A. From the Nuffield Institute for Medical Research, Oxford. Oxford: Blackwell. 1947. Pp. 187. 25s.

THIS monograph fulfils the promise given a year ago in the authors' preliminary note (*Lancet*, 1946, ii, 237), which briefly described experiments pointing to the existence of two alternative routes for the circulation of blood through the kidney. They now recount, lucidly and in detail, the experimental stages leading to this conclusion, beginning with the observation by Trueta and Barnes that constriction of one femoral artery by a tourniquet will lead, in the rabbit, to prolonged spasm not only of the constricted artery but of the artery of the opposite limb, and also a retrograde spasm of the proximal intra-abdominal segment of vessel extending as far back as the renal arteries. Having later shown this effect to be under nervous control they were able to observe, by the expert use of contrast media in radiography and accurate timing of the exposures, that, in the circumstances of these experiments, the passage of blood through the kidney seemed abnormally rapid. Further study led to the demonstration of a shunt mechanism in the kidney, and it is to the elucidation of this, and in particular the anatomy of the vascular pathways involved, that the main part of the work is devoted. The numerous excellent photographs illustrating the book testify to the skill and industry spent on the preparation of neoprene casts of the more delicate renal vessels: the results are both beautiful and convincing. Their study forms the basis of a new conception of the function of the medullary vessels, and it is reasonable to expect that physiologists and pathologists will revise all aspects of renal function both in health and in disease in the light of this work. Many of the problems involved are outlined in the final chapter; not the least fascinating is the suggestion that essential hypertension may prove to be based on a too oft-repeated cortical ischæmia, of a functional character, effected by the diversion of blood through the medullary pathway.

Though rabbits were mainly used in these experiments, the investigation of the intrarenal vascular pattern has been extended to a variety of other mammals, including man, with consistent results. If, as these suggest, the renal circulation obeys the same laws in man as in the rabbit the new concept will prove an important and revolutionary contribution to medical science.

the tendency to this deviation from normal function reflects a metabolic disturbance related to the ulcer diathesis. Improvement in dark-adaptation was observed after treatment with large doses of vitamin A (though the patients appeared generally rather resistant to this treatment) and after treatment with crude liver extract and brewers' yeast. Mention may be made here also of the observations of Boles and his colleagues (see Riggs et al. 1941), who found in ulcer patients subnormal levels of serum proteins which were apparently not correlated to dietary intake.

It has been pointed out that the disturbances in vitamin-A metabolism just mentioned are not simply dietary in origin (though they may be aggravated by primary deficiencies), since this fact (if correct) by itself points to a metabolic disorder which is the main theme of this paper; but there is obviously an indirect relation to dietary factors which may be considered in the treatment. The correction of what may be interpreted as "relative" or "conditioned" deficiency of vitamin A seems indicated, but more emphasis should be laid on the underlying disturbance—i.e., hepatic dysfunction—which is likely to cause more complex deficiencies. With regard to the latter, a diet rich in dairy and vegetable protein and carbohydrate, supplemented by brewers' yeast and/or crude liver extract, vitamins A and C, seems to be indicated and has been used with encouraging results by Patek (1937), Patek and Post (1941), and Fleming and Snell (1942) in the treatment of hepatic cirrhosis and for the preoperative treatment of patients with hepatic damage (Walters and Snell 1940). Usually liver function was rapidly restored in most patients on a standard ulcer régime, particularly in those under 45 years of age, but in selected cases such a therapy seemed to improve the synthesis of hippuric acid and to have a beneficial effect on general condition and postoperative course.

Evaluation of liver function is of importance in the preoperative management. The postoperative depression of hepatic function is more serious in patients with damaged livers, and in these patients the operative mortality is higher and the postoperative course less favourable (Graham et al. 1929, Kohlstaedt and Helmer 1936, Boyce 1941, Mateer 1943). The detection of impaired liver function, which may be clinically unsuspected, is believed to be of assistance in assessing the surgical risk and in selecting patients who may benefit from special preoperative treatment. Serial tests are of help in gauging the efficiency of such treatment and determining the best time for operation.

SUMMARY

Observations with Quick's hippuric-acid test, using Weichselbaum and Probstein's analytical method, indicated a tendency to moderately impaired liver function in a selected group of 67 male peptic-ulcer patients.

It is suggested that hepatic dysfunction, irrespective of its cause, and probably reflecting a disturbance in general metabolism, may lower the resistance of the gastroduodenal mucosa.

The importance of measuring liver function before operation is emphasised.

I wish to thank Dr. F. Avery Jones for his kind help in many ways; to Dr. G. Buchan, late medical officer of health for Willesden, for arranging for Civil Defence workers to serve as normal controls; and to the nursing staff of the dietary wards for their excellent coöperation.

STAPHYLOCOCCAL OSTEOMYELITIS OF SPINE IN A BABY AGED THREE WEEKS

P. G. FINCH
M.B. Lond., D.C.H.
LATE RESIDENT MEDICAL OFFICER, WIMBLEDON HOSPITAL

It is usually thought that osteomyelitis is rare in infancy, but Green and Shannon[1] collected 95 examples. It usually occurs in the long bones (e.g., the femur) and is very rare in the spine, the part affected in the following case.

The baby was 11 days old when first admitted to the Wimbledon Hospital. He had a mild pyrexia (up to 101°) for which no cause could be found. Throat, ears, chest, and urine appeared normal, but the tip of his right middle finger was rather red.

After a three-day course of penicillin (8000 units three-hourly intramuscularly; total 68,000) his temperature subsided and he started to gain weight, but the finger was more red and swollen. It was incised, pus was evacuated, and he was sent out after five days' stay in hospital. The finger healed within three or four days. No attempt was made to culture the pus.

Three weeks later he was readmitted with a history of having been quite well (he had gained 1 lb. 6 oz.) until a week before readmission, when he had a cold; two days later it was noted that he could not move his arms and screamed when his neck was moved.

On admission his general condition was good, but he had a complete flaccid paralysis of both arms, including shoulders and hands. The legs were strong though possibly a little stiff; cranial nerves and fontanelle tension were normal. The neck was held rigid, and the muscles at the back of the

IODOLYSIN
THIOSINAMINE ETHYL IODIDE
For
RHEUMATOID ARTHRITIS
AND ALLIED CONDITIONS
Thiosinamine 43%
Iodine 47%
40 Soluble Gelatine Capsules
IODOLYSIN
Trade Mark
Dose: One or more to be taken as directed by the physician
Manufactured in England by
ALLEN & HANBURYS LTD.
LONDON. E 2.

Iodolysin, a chemical combination of thiosinamine and ethyl iodide which has long had a reputation for the relief of rheumatoid arthritis and allied arthropathies, is again available for clinical use.

Administered orally in capsules, Iodolysin will often afford considerable relief from pain and allow freedom of movement of the affected joints.

Iodolysin Capsules are available in tins of 40 and 250 capsules.

Injuries and Diseases of the Œsophagus

G. GREY TURNER, M.S., F.R.C.S., Hon. F.A.C.S., professor of surgery in the University of London at the British Postgraduate Medical School. London: Cassell. 1946. Pp. 100. 15*s*.

THE œsophagus has held an increasing interest for surgeons in recent years, and Prof. Grey Turner deserves credit for helping to bring it into the field of surgical vision. This monograph of 100 pages, based on the George Haliburton Hume lectures delivered in Newcastle in 1943, does not attempt to treat exhaustively the abnormalities, injuries, and diseases of the œsophagus, but is a study of the approach and evolution of surgery in the subject. Case-reports, personal experience, reminiscence, and aphorism are blended with illustration to make the book read well. If carcinoma is not allotted much space, it is because this subject has been discussed fully by others. The treatment of congenital abnormalities is considered in detail, with recognition of the fact that only early and drastic measures will have any hope of success in cases of atresia. Many swallowed foreign bodies will pass through the narrow channel of the œsophagus, but occasionally a dangerously shaped object lodges there—an emergency which "knows no night, no day." No single remedy will serve either for fibrous stricture or achalasia; Prof. Grey Turner indicates the various forms of treatment which achieve success in different phases and degrees of the conditions. In cardiospasm, if more conservative measures fail, cardioplasty and œsophago-gastrostomy may be successful. Accounts are included of many rarer conditions, such as spontaneous rupture, peptic ulcer, pouches, and varices. Readers will find the author as stimulating as he himself found Haliburton Hume.

Surface and Radiological Anatomy

(2nd ed.) A. B. APPLETON, M.A., M.D., professor of anatomy, University of Liverpool; W. J. HAMILTON, M.D., D.SC., F.R.S.E., regius professor of anatomy, University of Glasgow; G. SIMON, M.D., D.M.R.E., assistant radiologist, X-ray diagnostic department, St. Bartholomew's Hospital, London. Cambridge: Heffer. 1946. Pp. 332. 31*s*. 6*d*.

THIS new edition can be read with pleasure, and the book is commended to all students and teachers of anatomy, as well as to general practitioners. It has been completely rewritten, though the purpose and general plan have not been altered. New illustrations have been included and many of the original ones modified; some of the half-tone diagrams are now coloured and this has made them much clearer. Mr. A. K. Maxwell, who is responsible for all the illustrations, contributes much to the value of this book, as he has done to many others. X-ray photographs have been replaced by a well-annotated new series of much better quality. Though the text is in the main pleasantly free of mistakes, the description of the action of the extrinsic eye muscles needs correction. Few other books on surface anatomy compare with this, mainly because, in it, surface features are constantly being related to deeper structures. It has, besides, what may be called the physiological approach: physical and radiological examination of the healthy living body gives information about normal structure and function which can never be gained by dissection of the cadaver. Physical examination of the disordered body and the interpretation of abnormal X-ray films are also considered in a useful way.

Studies on Impaired Fertility in Man

With Special Reference to the Male. RICHARD HAMMEN, translated by HANS ANDERSEN. Copenhagen: Munksgaard. London: Oxford University Press. 1944. Pp. 192. 10*s*.

THIS good monograph, presented in so readable a translation, merits careful study. During four years Dr. Hammen examined nearly 300 infertile couples and 1184 specimens of semen. He used accepted methods, but his painstaking and careful laboratory and clinical observations were all made personally, not deputed to others. He has explored the literature thoroughly up to 1940, and gives due weight to the findings of others; more recent work was inaccessible to him during the war. He regrets that in barren marriages the wife is still sometimes subjected to unnecessary examinations and even operations, while the husband is not even investigated. He believes that semen analysis offers the best means of assessing male fertility; and that, for proper assessment, estimations of volume, count, motility, viability, and morphology are more important than estimation of pH. He holds that measurement of the length of sperm heads, as advocated by Moench, does not yield information of enough value to justify the time it takes. Vital staining, and estimation of sperm metabolism, both of which he has tried, he thinks still too experimental to be of clinical value. His methods of estimating viability and of fixing and staining films for differential counts cannot entirely escape criticism, but his observations are certainly accurate and his deductions stimulating. He regards the commonly accepted norms as too high, being "ideal" rather than "average"; and he believes that the diagnosis of absolute sterility can be *made only* when spermatozoa are completely absent on repeated examinations. He disagrees with Moench that it is common to find one partner grossly at fault and the other adequately fertile: *far more commonly, he says, there are defects in both* and early adequate investigation of both partners is therefore essential. He says little about testicular biopsy, and the postcoital test is not mentioned. The section on examination of wives is short, and makes no reference to tuberculosis as a cause of tubal occlusion or of endometritis: is *Denmark* really so fortunate? Treatment, and response to treatment as revealed by semen analysis, are not discussed.

Gas and Air Analgesia (3rd ed. London: Baillière. 1947. Pp. 80. 5*s*.).—In his latest revision of this useful little handbook Dr. R. J. Minnitt has elaborated his advice on antenatal instruction. Though intended primarily for midwives, the book may be read with profit by practitioners and teachers.

Currents in Biochemical Research (New York: Interscience Publishers. 1946. Pp. 486. $5).—As the preface explains, this represents an attempt by some thirty research-workers, under the editorship of David E. Green, to describe simply important developments in such fields as the viruses, the nutrition and biochemistry of plants, vitamins, enzymes, hormones, isotopes, immunochemistry, and the like. It is a good reference book for chemists, biochemists, and doctors covering a wide field.

Our Inner Conflicts. *A Constructive Theory of Neurosis.* (London: Kegan Paul. 1947. Pp. 250. 10*s*. 6*d*.).—Psycho-analysis has not been lucky in its heresies and offshoots: Dr. Karen Horney's variant becomes, with each book she writes, more and more hard to distinguish from those easy little explanations of human nature which are designed to guide troubled people in their efforts at self-help and understanding. It is based, no doubt, on extensive clinical experience, and its avoidance of jargon is in its favour; but the reader confronted with so much philosophising and so little manifest concern with unconscious mental happenings, transference, and other familiar Freudian essentials, may wonder why Dr. Horney retains the name "psycho-analysis" for her methods and views; he may also wonder whether latter-day psychotherapy is developing on scholastic and literary rather than on scientific and medical lines.

Lehrbuch der Allgemeinen Kinderpsychiatrie (2nd ed. Basle: Schwabe. 1945. Pp. 517. Sw. fr. 32).—Dr. M. Tramer, of the University of Berne, gives an authoritative exposition of the general theory and practice of child psychiatry in Switzerland. Readers accustomed to the Anglo-American standpoint will find here frequent divergence from their habitual concepts and principles—startlingly exemplified in the chapter on treatment, which gets only 13 pages. The Swiss approach is less indebted to psycho-analysis, lays its emphasis on the thorough investigation and handling of environmental influences, and draws on a psychology of normal childhood which is substantially derived from W. Stern and Charlotte Bühler. The book is elaborate rather than comprehensive: *the less* concrete the matter under examination, the lengthier the exposition, whereas such clinical problems as schizophrenia in childhood receive relatively brief attention.

LONDON: SATURDAY, JULY 26, 1947

Food and the Worker

SINCE the middle thirties the International Labour Office has paid much attention to the nutrition of workers and their families. In 1935 the director wrote: "If it is agreed that the only real solution of he problem of economic balance is not through caling down production but in levelling up consumpion then it follows that the best hope of finding the way out of the present troubles is to raise the standards of the millions who are now underfed, underclothed, and under-equipped." This was written at a time when the economists were mostly saying that production must be restricted in order to raise primary prices—when coffee beans were being burned in Brazil and when farmers in at least one country were being paid a bonus for "not raising hogs"

Now that many people maintain that our reconstructive effort is weakened by deficiencies in diet[1] t is useful to have three essays on Nutrition in Industry,[2] dealing with conditions in Canada, the United States, and Great Britain In his introduction Dr. FRANK G. BOUDREAU, of the Millbank Memorial Fund, recalls that before the war the League of Nations and the I.L.O. did much to stimulate interest and national action in nutrition Precise information about the relationship between nutrition, health, and working efficiency was lacking, though the evidence pointed to a direct connexion between nutrition and output. But when war broke out the governments of the three countries all took early action to see that the industrial workers were properly fed—the first to do so being our own Neither in Canada nor in the United States did the departments dealing with workers' nutrition have powers to compel factory-owners to feed their employees; but in Great Britain from November, 1940, it was obligatory to provide canteens serving hot meals in all factories, works, and building sites employing 250 persons or more and engaged on war work on behalf of the Crown—which covered the vast majority. Nevertheless, it is evident that the success of the canteen movement did not depend entirely on compulsion, for in March, 1945, there were 6772 canteens in factories and similar places where fewer than 250 people were employed. Altogether by this time there were 12,245 industrial canteens. Though the Armed Forces were given high rations the justice of differential rationing in favour of heavy industrial workers was not really recognised until the war was over, and it was the general policy of the Ministry of Food to allow the maximum rations to all consumers rather than to give more to some at the expense of the remainder.[3] Part of the function of the industrial canteens and British Restaurants was to compensate for this absence of differential rationing.

Dr. L. B. PETT, who writes the Canadian section, says that "proteins also supply energy to the body, although the process is rather wasteful and proteins are therefore less important (than fats or carbohydrates) as energy producers." There can be no doubt, however, that men undertaking heavy physical labour believe that they need large quantities of meat, and the institution of meat rationing in the U.S.A. in 1943 brought immediate complaints from logging and other forest workers throughout the country. Inquiries into the amounts of food normally eaten in logging camps showed that the daily number of calories ranged from 5311 to 6425 per man: the day's intake included well over 1 lb. of meat, fish, and poultry, about $^1/_3$ lb. of eggs, and anything between 0·428 and 2·242 lb. of milk and milk products. Cheese does not seem to have been popular, for only 0·029 to 0·064 lb. was eaten. The loggers were convinced *that large amounts of meat at each meal are* necessary to keep up the pace of the heavy work required, and they regard as "side dishes" such delicacies as macaroni cheese, baked beans, creamed codfish, and scrambled eggs As a result of these and other inquiries the food and nutrition board of the U.S. National Research Council recommended a scheme of differential rationing for industrial workers, who for this purpose were put into four groups. In category I the loggers were in splendid isolation, and it was recommended that they should have over 5500 calories per day. Category II, with 4500–5500 calories, consisted of coal and ore miners, workers in foundries (including blast furnaces, steel works, and rolling mills), longshoremen, stevedores, and men engaged in engineering construction. Category III contained less arduous occupations and was assessed at 3000–4500 calories, while the workers in category IV, which included industries such as printing, textiles, tobacco, and food-processing, were to be given 3000 or less each day These recommendations, however, were implemented only for loggers and miners, and in addition increased allotments of food were made to "floating craft" and deep-sea fishermen according to certain criteria regarding isolation of the jobs.

We must hope that some day orders and regulations will lapse and war-time agencies will disappear; but we must see that the gains made in nutrition are not thrown away. A group of employers in the U.S.A. has resolved to continue the practice of feeding employees, "not so much for its influence on the health of the workers as for the improvement it brings about in the relations between management and labour." The hope is expressed that when a new factory canteens order is made for peace-time in Great Britain it will not be limited to factories employing over 250 persons. Experience after the 1914–18 war showed that workers at that time preferred to take their meals at home when possible, and many war-time canteens closed for lack of patronage; but habits sometimes change. It is stated that the average American worker is more "food and nutrition conscious" than he was before the war, and that both he and his family are eating better. The average British worker is likewise more food-conscious; but whether he and his family are eating better is a subject on which there is more than one opinion.

TRADE MARK

'THIAZAMIDE'

BRAND

sulphathiazole

Sulphathiazole is one of the most active of the sulphonamide drugs at present available for the treatment of pneumococcal, meningococcal, gonococcal and haemolytic streptococcal infections.

It is the sulphonamide of choice for the treatment of urinary tract infection, staphylococcal infections and gas gangrene. It is an effective chemotherapeutic agent in acute bacillary dysentery and in chancroid.

Supplies:

tablets of 0.125 Gm. and 0.50 Gm.
also available in cream, paste,
eye ointment and powder.

'**SOLUTHIAZOLE**' brand neutral soluble sulphathiazole derivative is recommended when parenteral administration is indicated.

May & Baker's sulphathiazole preparations are protected by British Patent No. 533,495, which was granted on 24 May, 1946, jointly to May & Baker Ltd., and Ciba Ltd. of Basle.

he fact that radiosodium (Na^{24}), when injected, is pidly distributed in the extra- and intra-vascular uids has been utilised to measure the arm-to-foot rculation-time, and thence, by observing the rate f accumulation of radiosodium at a given site, to stimate the efficiency of the circulation. SMITH nd QUINBY[7] have applied this technique to the udy of peripheral vascular disease of the lower mbs, and have found it helpful in deciding whether lumbar sympathectomy is likely to benefit cases of ypertension. The strontium isotope, Sr^{89}, which has half-life of 55 days and emits β^- rays, is taken up by steoplastic tissue and can be applied to the study of one metabolism. A newly prepared calcium isotope, Ca^{45}, with a half-life of 180 days, will also be useful for this purpose. Of great importance in organic chemistry and biochemistry is the discovery of the C^{14} isotope with a half-life of about 25,000 years, and H^3 with a half-life of 30 years; the previously known radiocarbon, C^{11}, was of little practical value because its half-life was only 20 minutes. The existence of a relatively stable labelled carbon atom opens up immense possibilities; as SEABORG puts it, "this field is so vast that it is certain that the best ideas are yet to come."

Enough has been said to indicate the tremendous importance of these isotopes for medical science. Such evidence as we have suggests that the therapeutic field is likely to be limited, and perhaps not too easy to control. It is in the prosecution of research that the new tools will be so valuable. Indeed, before long the biochemical department not equipped for isotope work will be as out of date as a pathological department without a microtome or an orthopædic department without an X-ray apparatus. The isotopes which emit γ rays will have to be handled carefully by those using them constantly, and safety rules must be drawn up before they become common. Meanwhile the radioactive isotopes are not easy to make, nor has the uranium pile solved all the problems of manufacture. But over a year ago the Manhattan Project published a long list of available isotopes,[8] and several are now obtainable in the United States in sufficient quantities for research and therapy. In this country the Medical Research Council—who control the distribution of isotopes—can offer only the most exiguous supplies. This is difficult to understand since published work from some Continental laboratories shows that they can obtain supplies from the U.S.A. Unless the position improves we must inevitably fall behind in this important branch of research.

Education of the Body

AMONG doctors and physiologists interest in physical education has mostly been desultory. Feats of strength, and athletic competitions, have always had their appeal—not least to those whose own endowments in such directions are meagre. But only comparatively recently has it occurred to research-workers that the physical performance of the spectators themselves can be vastly improved, with corresponding benefit to their health.

In South Africa and the United States a good deal has been done on these lines in the past ten years, and from the former country we now have a report by the medical research committee of the National Advisory Council for Physical Education.[1] Written by Dr. JOKL, it describes work which stems from the 1933–39 experience of reabling European unemployed at Roberts Heights by physical education within the framework of a paramilitary organisation.[2] The South African investigators have measured the heights, weights, chest circumferences, upper-arm circumferences, and hip widths of large number of white and Bantu children between the ages of 7 and 16, and they present the usual growth curves for these subjects.[3] The Bantu begin their adolescent spurt in growth considerably later than do white children studied elsewhere: how far this is due to heredity and how far to environment is not discussed, but other evidence indicates that malnutrition delays the appearance of the growth spurt and the menarche.[4] These children and others (including coloured, Indian, and Chinese) were given three tests of physical efficiency—the time taken to run 100 yards, the time taken to run 600 yards, and the distance that a 12 lb. shot could be put. Growth curves for each group are given for these items, which are said to measure respectively skill, endurance, and strength. The shot-put curve exhibits the well-known phenomenon of an increase of strength at puberty, as shown, for example, in the work of the Galton laboratory.[5] JOKL and his associates believe that, so far as running ability is concerned, puberty has an adverse effect, and that increase in efficiency "comes to a standstill with the onset of puberty"; but this conclusion conflicts with those reached in the University of California Adolescent Study.[6] In California it was found that the adolescent spurt in growth is associated with improvement in the times of track events—and indeed all athletic performance—as would be expected from the increased growth of the muscles. By the end of puberty, at about 13½ in girls and several years later in boys, adult standards are for the most part established, apart from practice and training effects; indeed girls' performances over the 50-yard dash worsened between the ages of 13 and 16. The time of the adolescent spurt varies from one child to another, and these physiological changes vary with it. Early maturers, who reach their maximum velocity of growth early and who menstruate early, settle down early to their adult standards for running and for pulling on the dynamometer, and adjust early to their adult levels for blood-pressure, heart-rate, and oxygen-consumption.[7] The sex difference in performance is also largely due to the adolescent spurt: before this time, boys are but slightly better than girls, but the growth spurt is much greater for boys, and it brings muscular superiority. A second look at JOKL's data shows that they are in fact consistent with these findings; it is only the interpretations that differ. In view of the predominance of negroes in athletic sports it is interesting to note that in the running events the Bantu children, despite their worse

Isotopes and Their Applications

THE discovery that isotopic forms of common elements could be used as "tracers" to follow the course of marked atoms through biological processes promises to open up as many new fields of medical research as did the development of histological techniques in the last century. Just as the gunner mixes tracer shells with the others to tell him where his missiles are going, so the biochemist and pharmacologist can substitute readily distinguishable isotopes for the ordinary constituent elements of foods and drugs and so determine their fate in the body. Radioactive isotopes can also be used therapeutically; in virtue of their property of emitting β and γ radiation they can be used to deliver what are, in effect, small but steady doses of X rays or radium in areas where they are concentrated. Summaries of present knowledge have been appearing in the American journals,[1] and Prof. ROBLEY EVANS and Dr. J. G. HAMILTON have lately been talking on the subject to interested groups in this country.[2]

Two forms of isotopes are being used in medical research. The first type comprises elements with the same nuclear charge as the parent elements but *different atomic weights*. For example, there are four such isotopes of iron—Fe^{54}, Fe^{56}, Fe^{57}, and Fe^{58}, the common one being Fe^{56}; others are H^2 (heavy hydrogen or deuterium), N^{15}, and C^{13}. These isotopes are not radioactive and are stable. Their presence in any material is determined by means of the mass spectrograph, and their distribution in the tissues can be followed if samples of tissue can be obtained for estimation. The second type, much more easily handled and therefore more widely used, is the radioactive isotope; such an isotope not only differs from the parent element in atomic weight but also emits radioactive rays in the same way as the radium group. Many radioactive isotopes have been manufactured in the cyclotron during the last decade, and more recently the uranium pile has allowed much larger quantities to be prepared. Radioactive isotopes of almost every known element have been made, but only elements with a suitable "half-life" are useful in medicine, and only those that have some place in biological metabolism are likely to give interpretable results. The radioactive isotopes that have been used in medicine include radio-iodine (I^{131}), half-life 8 days, emitting β^- and γ rays; radiophosphorus (P^{32}), half-life 14 days, emitting β^- rays; radiosodium (Na^{24}), half-life 14·8 hours, emitting β^- and γ rays; radiocarbon (C^{14}), half-life 25,000 years, emitting β^- rays; and radio-iron (Fe^{59}), half-life 47 days, emitting β^- and γ rays. With the exception of radiophosphorus, other less useful radioactive isotopes of all these elements exist; hence the necessity of referring not merely to radio-iodine but to I^{131}—i.e., the radioactive isotope of iodine with atomic weight 131.

The detection and measurement of the radioactive isotopes can be done in three ways. An in-vitro method applicable to tissues is to ash the tissues, or blood samples, and then estimate radioactivity with a Geiger counter or an electrometer; or the radioactive element can be attracted on to a suitably charged plate and then estimated.[3] An in-vivo method is to apply a Geiger counter over the organ where concentration of the radioactive element is suspected; suitably shaped counters have been developed for this work. A third method is to make frozen sections of a tissue or group of tissues, place in contact with a sensitive photographic plate, and then develop the resulting picture. The first and third of these methods give direct results; but the second method, using specimens of blood or tissue, allows of considerable mechanisation, and Prof. ROBLEY EVANS describes machines that will assay the radioactivity of samples—and record the results—in batches of dozens at a time.

Of the isotopes so far used in therapy and medical research, most is known about those of phosphorus, iron, iodine, and sodium, and C^{14} as applied to biochemistry. Radiophosphorus therapy, which was reviewed here last April,[4] has given its best results in polycythæmia vera and chronic myeloid leukæmia, in other conditions it has proved unsatisfactory. Another suggested application of radiophosphorus is based on its tendency to become concentrated in *rapidly growing tissues and therefore* in malignant growths. In the diagnosis of malignant tumours LOW-BEER and others [5] give a dose of radiophosphate and then record the concentration of P^{32} with a Geiger counter placed over the tumour. The β-rays emitted are relatively rapidly absorbed by tissues so the technique is limited to tumours near the body surface, but it has possibilities. Labelled phosphorus is being used to explore again the biochemistry of the phospholipids and the rôle of phosphorylated compounds in carbohydrate metabolism. It has also been used to "tag" tubercle bacilli. Studying iron metabolism by means of radio-iron, WHIPPLE and his school have confirmed the earlier view that the amount of iron absorbed depends on bodily needs, and that once it is absorbed little is excreted. It has been shown that iron given to an anæmic subject is utilised, almost quantitatively, for the formation of hæmoglobin. VANNOTTI [6] in Switzerland has shown that radio-iron injected intravenously is temporarily stored in the liver but gradually released for the formation of hæmoglobin. The survival of red blood-cells has also been estimated by means of radio-iron. Radio-iodine has naturally found its place in the study of thyroid metabolism, and I^{131} has been used in the therapy of thyroid disorders. It has been shown that a normal person excretes about 80% of a dose of iodine, and a myxœdematous patient about 95%, whereas a hyperthyroid patient retains much more. I^{131} emits both β and γ rays, and when doses of it are retained in an overactive thyroid they produce an effect like X rays. It has given good results in toxic goitre, and ROBLEY EVANS has reported that a single dose of 40–50 millicuries will produce a maximum remission in about two months with effects lasting much longer; remissions have been obtained in patients resistant to thiouracil. *A few patients* with thyroid cancer have been treated, some successfully; in one successful case, bony metastases also responded

Feats of strength, and athletic competitions, have always had their appeal—not least to those whose own endowments in such directions are meagre. But only comparatively recently has it occurred to research-workers that the physical performance of the spectators themselves can be vastly improved, with corresponding benefit to their health.

In South Africa and the United States a good deal has been done on these lines in the past ten years, and from the former country we now have a report by the medical research committee of the National Advisory Council for Physical Education.[1] Written by Dr. JOKL, it describes work which stems from the 1933–39 experience of reabling European unemployed at Roberts Heights by physical education within the framework of a paramilitary organisation.[2] The South African investigators have measured the heights, weights, chest circumferences, upper-arm circumferences, and hip widths of large number of white and Bantu children between the ages of 7 and 16, and they present the usual growth curves for these subjects.[3] The Bantu begin their adolescent spurt in growth considerably later than do white children studied elsewhere: how far this is due to heredity and how far to environment is not discussed, but other evidence indicates that malnutrition delays the appearance of the growth spurt and the menarche.[4] These children and others (including coloured, Indian, and Chinese) were given three tests of physical efficiency—the time taken to run 100 yards, the time taken to run 600 yards, and the distance that a 12 lb. shot could be put. Growth curves for each group are given for these items, which are said to measure respectively skill, endurance, and strength. The shot-put curve exhibits the well-known phenomenon of an increase of strength at puberty, as shown, for example, in the work of the Galton laboratory.[5] JOKL and his associates believe that, so far as running ability is concerned, puberty has an adverse effect, and that increase in efficiency "comes to a standstill with the onset of puberty"; but this conclusion conflicts with those reached in the University of California Adolescent Study.[6] In California it was found that the adolescent spurt in growth is associated with improvement in the times of track events—and indeed all athletic performance—as would be expected from the increased growth of the muscles. By the end of puberty, at about 13½ in girls and several years later in boys, adult standards are for the most part established, apart from practice and training effects; indeed girls' performances over the 50-yard dash worsened between the ages of 13 and 16. The time of the adolescent spurt varies from one child to another, and these physiological changes vary with it. Early maturers, who reach their maximum velocity of growth early and who menstruate early, settle down early to their adult standards for running and for pulling on the dynamometer, and adjust early to their adult levels for blood-pressure, heart-rate, and oxygen-consumption.[7] The sex difference in performance is also largely due to the adolescent spurt: before this time, boys are but slightly better than girls, but the growth spurt is much greater for boys, and it brings muscular superiority. A second look at JOKL's data shows that they are in fact consistent with these findings; it is only the interpretations that differ. In view of the predominance of negroes in athletic sports it is interesting to note that in the running events the Bantu children, despite their worse

Isotopes and Their Applications

THE discovery that isotopic forms of common elements could be used as "tracers" to follow the course of marked atoms through biological processes promises to open up as many new fields of medical research as did the development of histological techniques in the last century. Just as the gunner mixes tracer shells with the others to tell him where his missiles are going, so the biochemist and pharmacologist can substitute readily distinguishable isotopes for the ordinary constituent elements of foods and drugs and so determine their fate in the body. Radioactive isotopes can also be used therapeutically; in virtue of their property of emitting β and γ radiation they can be used to deliver what are, in effect, small but steady doses of X rays or radium in areas where they are concentrated. Summaries of present knowledge have been appearing in the American journals,[1] and Prof. ROBLEY EVANS and Dr. J. G. HAMILTON have lately been talking on the subject to interested groups in this country.[2]

Two forms of isotopes are being used in medical research. The first type comprises elements with the same nuclear charge as the parent elements but different atomic weights. For example, there are four such isotopes of iron—Fe^{54}, Fe^{56}, Fe^{57}, and Fe^{58}, the common one being Fe^{56}; others are H^{2} (heavy hydrogen or deuterium), N^{15}, and C^{13}. These isotopes are not radioactive and are stable. Their presence in any material is determined by means of the mass spectrograph, and their distribution in the tissues can be followed if samples of tissue can be obtained for estimation. The second type, much more easily handled and therefore more widely used, is the radioactive isotope; such an isotope not only differs from the parent element in atomic weight but also emits radioactive rays in the same way as the radium group. Many radioactive isotopes have been manufactured in the cyclotron during the last decade, and more recently the uranium pile has allowed much larger quantities to be prepared. Radioactive isotopes of almost every known element have been made, but only elements with a suitable "half-life" are useful in medicine, and only those that have some place in biological metabolism are likely to give interpretable results. The radioactive isotopes that have been used in medicine include radio-iodine (I^{131}), half-life 8 days, emitting β^- and γ rays; radiophosphorus (P^{32}), half-life 14 days, emitting β^- rays; radiosodium (Na^{24}), half-life 14·8 hours, emitting β^- and γ rays; radiocarbon (C^{14}), half-life 25,000 years, emitting β^- rays; and radio-iron (Fe^{59}), half-life 47 days, emitting β^- and γ rays. With the exception of radiophosphorus, other less useful radioactive isotopes of *all* these elements *exist*; *hence the* necessity of referring not merely to radio-iodine but to I^{131}—i.e., the radioactive isotope of iodine with atomic weight 131.

The detection and measurement of the radioactive isotopes can be done in three ways. An in-vitro method applicable to tissues is to ash the tissues, or blood samples, and then estimate radioactivity with a Geiger counter or an electrometer; or the radioactive element can be attracted on to a suitably charged plate and then estimated.[3] An in-vivo method is to apply a Geiger counter over the organ where concentration of the radioactive element is suspected; suitably shaped counters have been developed for this work. A third method is to make frozen sections of a tissue or group of tissues, place it in contact with a sensitive photographic plate, and then develop the resulting picture. The first and third of these methods give direct results; but the second method, using specimens of blood or tissue, allows of considerable mechanisation, and Prof. ROBLEY EVANS describes machines that will assay the radioactivity of samples—and record the results—in batches of dozens at a time.

Of the isotopes so far used in therapy and medical research, most is known about those of phosphorus, iron, iodine, and sodium, and C^{14} as applied to biochemistry. Radiophosphorus therapy, which was reviewed here last April,[4] has given its best results in polycythæmia vera and chronic myeloid leukæmia: in other conditions it has proved unsatisfactory. Another suggested application of radiophosphorus is based on its tendency to become concentrated in rapidly growing tissues and therefore in malignant growths. In the diagnosis of malignant tumours LOW-BEER and others[5] give a dose of radiophosphate and then record the concentration of P^{32} with a Geiger counter placed over the tumour. The β-rays emitted are relatively rapidly absorbed by tissues, so the technique is limited to tumours near the body surface, but it has possibilities. Labelled phosphorus is being used to explore again the biochemistry of the phospholipids and the rôle of phosphorylated compounds in carbohydrate metabolism. It has also been used to "tag" tubercle bacilli. Studying iron metabolism by means of radio-iron, WHIPPLE and his school have confirmed the earlier view that the amount of iron absorbed depends on bodily needs, and that once it is absorbed little is excreted. It has been shown that iron given to an anæmic subject is utilised, almost quantitatively, for the formation of hæmoglobin. VANNOTTI[6] in Switzerland has shown that radio-iron injected intravenously is temporarily stored in the liver but gradually released for the formation of hæmoglobin. The survival of red blood-cells has also been estimated by means of radio-iron. Radio-iodine has naturally found its place in the study of thyroid metabolism, and I^{131} has been used in the therapy of thyroid disorders. It has been shown that a normal person excretes about 80% of a dose of iodine, and a myxœdematous patient about 95%, whereas a hyperthyroid patient retains much more. I^{131} emits both β and γ rays, and when doses of it are retained in an overactive thyroid they produce an effect like X rays. It has given good results in toxic goitre, and ROBLEY EVANS has reported that a single dose of 40–50 millicuries will produce a maximum remission in about two months with effects lasting much longer; remissions have been obtained in patients resistant to thiouracil. A few patients with thyroid cancer have been treated, some successfully; in one successful case, bony metastases also responded.

The fact that radiosodium (Na^{24}), when injected, is rapidly distributed in the extra- and intra-vascular fluids has been utilised to measure the arm-to-foot circulation-time, and thence, by observing the rate of accumulation of radiosodium at a given site, to estimate the efficiency of the circulation. Smith and Quinby[7] have applied this technique to the study of peripheral vascular disease of the lower limbs, and have found it helpful in deciding whether a lumbar sympathectomy is likely to benefit cases of hypertension. The strontium isotope, Sr^{89}, which has a half-life of 55 days and emits β^- rays, is taken up by osteoplastic tissue and can be applied to the study of bone metabolism. A newly prepared calcium isotope, Ca^{45}, with a half-life of 180 days, will also be useful for this purpose. Of great importance in organic chemistry and biochemistry is the discovery of the C^{14} isotope with a half-life of about 25,000 years, and H^3 with a half-life of 30 years; the previously known radiocarbon, C^{11}, was of little practical value because its half-life was only 20 minutes. The existence of a relatively stable labelled carbon atom opens up immense possibilities; as Seaborg puts it, "this field is so vast that it is certain that the best ideas are yet to come."

Enough has been said to indicate the tremendous importance of these isotopes for medical science. Such evidence as we have suggests that the therapeutic field is likely to be limited, and perhaps not too easy to control. It is in the prosecution of research that the new tools will be so valuable. Indeed, before long the biochemical department not equipped for isotope work will be as out of date as a pathological department without a microtome or an orthopædic department without an X-ray apparatus. The isotopes which emit γ rays will have to be handled carefully by those using them constantly, and safety rules must be drawn up before they become common. Meanwhile the radioactive isotopes are not easy to make, nor has the uranium pile solved all the problems of manufacture. But over a year ago the Manhattan Project published a long list of available isotopes,[8] and several are now obtainable in the United States in sufficient quantities for research and therapy. In this country the Medical Research Council—who control the distribution of isotopes—can offer only the most exiguous supplies. This is difficult to understand since published work from some Continental laboratories shows that they can obtain supplies from the U.S.A. Unless the position improves we must inevitably fall behind in this important branch of research.

Education of the Body

Among doctors and physiologists interest in physical education has mostly been desultory. Feats of strength, and athletic competitions, have always had their appeal—not least to those whose own endowments in such directions are meagre. But only comparatively recently has it occurred to research-workers that the physical performance of the spectators themselves can be vastly improved, with corresponding benefit to their health.

In South Africa and the United States a good deal has been done on these lines in the past ten years, and from the former country we now have a report by the medical research committee of the National Advisory Council for Physical Education[1] Written by Dr. Jokl, it describes work which stems from the 1933–39 experience of reabling European unemployed at Roberts Heights by physical education within the framework of a paramilitary organisation.[2] The South African investigators have measured the heights, weights, chest circumferences, upper-arm circumferences, and hip widths of large number of white and Bantu children between the ages of 7 and 16, and they present the usual growth curves for these subjects.[3] The Bantu begin their adolescent spurt in growth considerably later than do white children studied elsewhere: how far this is due to heredity and how far to environment is not discussed, but other evidence indicates that malnutrition delays the appearance of the growth spurt and the menarche.[4] These children and others (including coloured, Indian, and Chinese) were given three tests of physical efficiency—the time taken to run 100 yards, the time taken to run 600 yards, and the distance that a 12 lb. shot could be put. Growth curves for each group are given for these items, which are said to measure respectively skill, endurance, and strength. The shot-put curve exhibits the well-known phenomenon of an increase of strength at puberty, as shown, for example, in the work of the Galton laboratory.[5] Jokl and his associates believe that, so far as running ability is concerned, puberty has an adverse effect, and that increase in efficiency "comes to a standstill with the onset of puberty"; but this conclusion conflicts with those reached in the University of California Adolescent Study.[6] In California it was found that the adolescent spurt in growth is associated with improvement in the times of track events—and indeed all athletic performance—as would be expected from the increased growth of the muscles. By the end of puberty, at about 13½ in girls and several years later in boys, adult standards are for the most part established, apart from practice and training effects; indeed girls' performances over the 50-yard dash worsened between the ages of 13 and 16. The time of the adolescent spurt varies from one child to another, and these physiological changes vary with it. Early maturers, who reach their maximum velocity of growth early and who menstruate early, settle down early to their adult standards for running and for pulling on the dynamometer, and adjust early to their adult levels for blood-pressure, heart-rate, and oxygen-consumption.[7] The sex difference in performance is also largely due to the adolescent spurt: before this time, boys are but slightly better than girls, but the growth spurt is much greater for boys, and it brings muscular superiority. A second look at Jokl's data shows that they are in fact consistent with these findings; it is only the interpretations that differ. In view of the predominance of negroes in athletic sports it is interesting to note that in the running events the Bantu children, despite their worse

economic and nutritional circumstances, were slightly superior to the whites.

An extensive clinical survey of Bantu children suggested that the chief cause of their medical defects, which were many, was malnutrition. Among Moslem Indian children it was found that running and weight-putting efficiency decreased during the fasting month of Ramadan, when the children had nothing to eat between an early breakfast and the time of their test. Another noteworthy observation was that "physically substandard" adolescent boys gained more weight during a nine months' physical-training course than normal boys of the same weight would have done, without training, in the same period. On the question whether physical training can harm the hearts of young people JOKL concludes that it cannot; in the reported sudden deaths of supposedly healthy men during or after athletic performances some other pathological change entirely unconnected with activity can always, he says, be demonstrated. A discussion on the philosophy of physical fitness includes a statement that the psychologist who took part in the investigation concluded that girls are superior in "morality" to boys. "There is a sudden marked drop in morality scores in boys when they become 13 years old. Girls do not show such a drop. They continue to progress steadily upward notwithstanding the fact that at the same time their physical performance scores remain behind those achieved by boys, or even decline."

More comprehensive work on physical-fitness tests has lately appeared from the University of Illinois school of physical education, in a monograph by CURETON et al.[8] who have analysed the repeatabilities and interrelationships of 28 tests of physical endurance, mostly of gymnastic type, but including several running events. The statistical technique used is factor analysis, and a combination of scores in 4 tests—chinning the bar, backward leg-raisings, side leg-raisings, and the mile run—has been found which can be used to evaluate a given person's overall endurance capacity. Further analysis shows that the tests fall together in groups: factors of running endurance, of lateral muscles, of shoulder-girdle and pelvic-girdle muscles (which go together, as one might expect), and of arm-extensor muscles emerge. CURETON also goes in detail into the endurance relationships of the Harvard step test (pulse-rate after stepping up on to a bench and down again 30 times a minute for five minutes) and the old Schneider index (a combination of lying pulse-rate, standing pulse-rate, pulse-rate change from lying to standing, pulse-rate increase after exercise, time for pulse to return to first value after exercise, and change in systolic blood-pressure from lying to standing). Analysis of the Schneider index shows that two of its items contribute no further information after the other four have been considered, and a modified index is presented which omits pulse-rate and blood-pressure change from lying to standing. This modified index predicts ability in running endurance (an average of 4 scores, for 1-mile run, 2-mile run, $3^1/_2$-mile steeplechase, and 1000-yard run) fairly well, but only for a group of men who are keen to do their best, and who are neither very fat nor very thin. Body build turns out to have a great deal to do with endurance in running; in the Sheldon terminology,[9] endomorphy decreases and ectomorphy increases it—i.e., fatness worsens performance and slimness improves it. Running endurance depends on motivation, skill, physique, and cardiovascular condition: the modified Schneider index measures, imperfectly, only the last of these. Thus the search for measures of physical fitness is being continued partly in the schools of physical education and in the field, where tests are devised, large numbers are tested, and training may be carried out, and partly in the physiological laboratories, where the effects of exercise itself are slowly being unravelled.

Annotations

EQUALITY IN SERVICE

IN a letter to *The Scotsman* of July 12, Prof. Mary Lucas Keene regrets, on behalf of the Medical Women's Federation, that the National Service Act, 1947, makes a distinction between men and women doctors by enforcing conscription on one and not on the other. Within the profession the principle of equality between the sexes is so well accepted that discrimination of this kind naturally appears somewhat arbitrary and irrational. Prof. Lucas Keene notes that some men have been provoked to contrast their position with the freedom of the women, while women seeking posts in competition with men who have given national service are placed at a disadvantage which they have done nothing to incur. The letter mentions a resolution, unanimously passed by the federation, asking that the National Service Act shall be so amended that its provisions apply to all members of the medical profession. While most medical men will sympathise with this protest, and the motives which gave rise to it, it is hard to see how the Government could select one group of women for national service while ignoring the rest. The principle of equality between the sexes should include equality of service as well as of privilege; but until this is generally accepted, as it should be, it seems likely that women doctors will appeal in vain against their unwanted freedom from conscription.

EPILEPSY AND EDUCATION

LESS than twenty years ago a Bill was proposed for the State legislature of Maryland whereby all epileptic children were to be excluded from the State schools. Fortunately medical opposition, emanating from the epilepsy clinic of the Johns Hopkins Hospital, was not wanting, and in the event all Baltimore children who suffered from fits were referred to that clinic, and were there graded as suitable for an ordinary education, or for home instruction, or as unfit for any education at all. No child was, however, retained in a State school if he had more than two major fits in the classroom during a five months' term. The story of the subsequent development of the clinic with its study of the individual child and its attempts to educate parents and teachers is told by Olive Whilden of the Baltimore education department, contributing to an American symposium on Epilepsy in Childhood.[10] Here we may learn how the problems of education and treatment are being met in the United States, where special schools for epileptic children are almost unknown. C. Bradley describes the care of epileptics in a residential hospital for children with neuropsychiatric disorders, and E. Davidoff sets out at length a programme for the medical and educational treatnt of epileptic children at the Craig Colony, a State titution for epileptics, which has, however, to cater all grades from the idiot upwards. For the most rt, indeed, as H. Yannet of the Southbury Training ool tells us, epileptic children who need institutional atment are found in State training schools for the ntally defective. The case for the English plan providing special residential schools for educable leptics is set out by Tylor Fox.

[10] *Nervous Child* (Child Care Publications, Baltimore), 194 6, no. 1.

Abnormalities of temperament and conduct get their r share of notice in this symposium. Edward Bridge, ector of the Johns Hopkins clinic, discussing emotional turbances in epileptic children, asserts that while ver than 1 in 10 of the children show serious personality orders at their first attendance, these disorders tend increase later, and in fact prove a larger handicap in ter-school careers than do the fits themselves. While ey rarely precede, or are associated with, the onset of s; they often encourage their occurrence, thus adding aterially to the children's physical and social handicap. ith expert advice and team-work, much could be done keep temperament and conduct nearer the normal. ne paper discusses the attitude of the epileptic child to s own complaint; another finds that the Rorschach st discloses characteristic and distinct personalities r sufferers from grand mal and from petit mal. But ost of the 30 children on whom this last investigation as made were attending a behaviour clinic; and this ows once more the necessity, before venturing on neralisations about epilepsy, of specifying as exactly possible the type of epileptic concerned. On the urological side balance is to some extent maintained y a paper on the neuropathology of epilepsy in children, nd by one of W. G. Lennox's masterly communications n drug therapy.

Everyone interested in epileptic children will do well o obtain this journal for himself and read and re-read he various papers. They are of course unequal, and here may be a good deal to criticise; but we all have omething to learn in a field which is inadequately overed by medical textbooks. We shall at least be onvinced that American workers recognise the great nportance, and often the great difficulty, of getting the ight lay staff for schools for epileptics. This applies ot only to teaching staff, but more especially to those hom the Americans aptly and picturesquely call "cottage heads."

VITAMIN A IN LEUCOPLAKIA

GYNÆCOLOGISTS do not always agree on what constitutes leucoplakia vulvæ, and it is probably fairest to iagnose this condition after histological examination f a biopsy specimen. Before diagnosing leucoplakia yams and Bloom[1] insist that such a specimen should how thickening of the epidermis, hyperkeratosis, and vergrowth of all layers with acanthosis; the dermis hould present a chronic inflammatory picture with an nvasion of chronic inflammatory cells. They investigated 18 patients in an attempt to find some common actor in the ætiology. In 11 of their cases they found ypochlorhydria or achlorhydria, all other tests being egative. For a similar age-group the incidence of ypochlorhydria is 35%, but whether the increase of 5% is significant in 18 cases is doubtful. They suggest hat a low gastric acidity interferes with the proper bsorption and utilisation of vitamin A, and for this eason they treated their patients with a daily dose of 50,000–500,000 units of vitamin A by mouth, supplemented by 50,000 units by injection twice weekly. n addition they gave ♏15 of dilute hydrochloric acid n water three times daily with each meal. The response o this treatment was slow, but in 14 cases they obtained definite improvement, both clinically and histologically. The dry indurated glossy and wrinkled external genitals became more pliable and normal. They have had 6 of their patients under observation for two years without any further treatment and with no recurrence.

This small series is published to stimulate interest among other clinicians. In a chronic condition which is resistant to almost all treatment except wide excision, and which may often then recur in regions adjacent to the site of the operation, any new suggestion is welcome. Œstrogen treatment, which has been suggested in the past and has no scientific basis, has been abandoned by most gynæcologists, so vitamin A and hydrochloric acid will have a relatively clear field. It can do no harm and it may do good. But it is important before assessing the results to be histologically certain of the diagnosis.

PINS AND NEEDLES

THE symptom involving the extremities which patients commonly call "pins and needles" comprises many different sensations. Though the main cause of the symptom may become apparent from a careful history and examination of the patient, very little is known about the mechanism of its production.

In a fascinating study of the subjective effects of compressing the arm with a sphygmomanometer cuff, Weddell and Sinclair[1] have advanced our knowledge of this mechanism. In a number of trained observers the cuff was inflated to a pressure of 150 mm. Hg for varying periods, with the arm hanging by the side after inflation of the cuff, and the resulting sensations analysed. One to two minutes after compression started a sensation termed "compression tingling" appeared, and this lasted for three to four minutes, passing off gradually. It consisted in a light tingling sensation more picturesquely described as "a faint comfortable soda-water sensation": though there might be a few sharp pricks, the main effect was of touch rather than of pain, and the sensation was not modified by external stimuli such as touching or rubbing the fingers. About a quarter of an hour after compression started a "velvety numbness" was experienced; this was at first only elicited when the hand was stroked, but it soon became spontaneous and gave rise to a peculiarly unpleasant subjective sensation of a sickening character. The third type of sensation occurred after release of the compression and has been named "release pricking." It first appeared about 45 seconds after release, and it lasted for a variable time, depending on the length of compression: it was a very strong coarse pricking, having a component of many sharp bright pricks like a needle entering the skin, and was interpreted subjectively as pain rather than touch, though there was a continuous diffuse tingling in addition to the pricking. The sensation was increased by tapping or rubbing the affected fingers.

"Compression tingling" and "release pricking" were studied by simple modifications of the technique of compressing the arm in an effort to discover their cause. It was noted that in 3 out of 16 subjects compression tingling was felt only in the ulnar distribution, in 2 in the tip of the thumb as well, while in 3 others it started in the ulnar distribution and spread to involve the rest of the palm of the hand and fingers.

The final conclusion was that compression tingling is due to local stimulation of the main nerves under the compression cuff, and that the stimulation is brought about by asphyxia rather than by deformation. It was thought to be due to impulses arising in fibres normally conveying the sense of touch. Release pricking begins in the finger-tips and spreads to involve the palm and (after protracted compression) the lower part of the forearm, the upper border being roughly horizontal; it is never confined to the distribution of a single peripheral nerve. It is thought to arise by an entirely different mechanism from compression tingling—stimulation of some of the peripheral nerve-endings by removal from the tissue spaces around them of a chemical substance which accumulates during a period of circulatory depression, the greater proportion of the impulses aroused in this way being conveyed in the somatic afferent fibres normally subserving the sensation of pain. The occurrence of release pricking runs parallel to that of reactive hyperæmia, which was shown by Lewis [2] to be due to the accumulation of a normal product of tissue metabolism in the tissue spaces.

A DRUG FOR HYPERTENSION

In the United States interest in the possible clinical value of tetra ethyl ammonium bromide (T.E.A.B.), a quarternary ammonium compound, was aroused by the discovery that intravenous injection in animals caused a sharp fall in systolic and diastolic blood-pressure and an increase in peripheral blood-flow, and that these effects resulted from a blockade of both sympathetic and parasympathetic ganglia.[3] Lyons et al.[4] reported preliminary results in about 700 patients given T.E.A.B. on one or more occasions. There were no deaths and only a few severe toxic reactions. Measurement of skin temperature and clinical response in patients with vascular disease and in a control group of healthy people suggested that T.E.A.B. was usually as effective or more so than the accepted surgical methods (paravertebral sympathetic block, local nerve block, spinal anæsthesia, and sympathectomy) of producing sympathetic block. This report and subsequent ones [5 6] indicate that T.E.A.B. is valuable in the treatment of peripheral vascular disease of all kinds (particularly when a vasospastic condition is present) and hypertensive congestive cardiac failure, and as a diagnostic aid for gauging the extent of the functional element in various vascular diseases.

The drug has also been used as a therapeutic test for the selection of patients likely to benefit from sympathectomy, but Birchall et al.[7] say that though T.E.A.B. produced an appreciable fall of blood-pressure in 14 out of 16 hypertensive patients, only 2 out of 12 of these patients who were subsequently subjected to lumbo-dorsal sympathectomy had any significant change in blood-pressure two to four weeks after the operation. Lyons et al.[6] comment on the symptomatic relief obtained when T.E.A.B. is given to hypertensive patients. One patient with hypertensive congestive cardiac failure and severe orthopnœa obtained relief for as long as twelve hours after one intramuscular injection. In general the symptomatic relief in hypertensive cardiac failure has been confirmed by workers in this country. Unfortunately, however, the fall in blood-pressure usually lasts for only ten or fifteen minutes after intravenous injection, and for an hour or so after intramuscular injection. The discovery of a suitable depot-forming substance that would release T.E.A.B. slowly into the circulation after intramuscular injection would be of great value.

The dose of T.E.A.B. is 0·1–0·5 g. intravenously or up to 20 mg. per kg. body-weight intramuscularly; it is unsuitable for administration by mouth because it is poorly absorbed from the gastro-intestinal tract. The drug is soluble in water and can be sterilised by autoclaving. A 10% aqueous solution has been recommended [6] for injection. It is estimated in urine by precipit with ammonium reineckate, as in the estimation choline.[6 8] Tetra ethyl ammonium chloride has been instead of T.E.A.B., and Birchall et al.[7] find that sedative effect of the bromide ions can thus be avoi

Although care is required in the administration T.E.A.B., severe toxic reactions are rare. A rapid profound drop in blood-pressure has been noted in cases and may cause grave circulatory collapse. drug should be used with particular caution in case severe hypertension, especially where renal functio impaired. Protracted use has been reported to anterior horn cell irritation, but this has not observed in Britain. Some patients find it gives th metallic taste in the mouth. Other effects are incom dilatation of the pupil and a decrease in its light reac ptosis, cessation of sweating, dry mouth, and dysph Bladder tone may become diminished and the desir micturate be suppressed. In the gastro-intestinal T.E.A.B. causes a cessation of propulsive motility a reduction of the acidity and volume of gastric j Peptic-ulcer patients are completely relieved of th symptoms, but once the effect of the drug wears off p stalsis returns (and the pain) with renewed force a vigour. *All these actions are due to the blockade* sympathetic and parasympathetic ganglia. In some c T.E.A.B. has relieved the pain of coronary thromb and angina pectoris, but Lyons and colleagues do advise its use in these conditions until further work been done on its effect on the coronary arteries.

STREPTOMYCIN IN PLAGUE

Streptomycin is active in vitro against a wide var of gram-negative organisms, and in practice it has prov effective in the treatment of some penicillin-resist infections, including tularæmia, tuberculous meningit *Hæmophilus influenzæ* meningitis, and contaminat wounds. 'The drug may have a further valuable app cation in the treatment of bubonic plague, the dread Black Death of the Middle Ages, of which 11 cases we reported at Haifa at the beginning of this month.' In an outbreak that occurred last winter at Buenos Aire according to a British United Press report, the firs 2 cases were treated with streptomycin, and though th prognosis appeared to be hopeless the patients survived. Two swallows do not make a summer, but such results would not be unexpected. During the prelimin bacteriological screening tests made shortly after th discovery of streptomycin it was found to inhibit th growth of *Pasteurella pestis.* Last year Hornibrook[10] and Wayson and McMahon[11] reported that they had prolonged the life and increased the survival-rate of mice and guineapigs infected with plague by treating them with streptomycin. This work has been confirmed and extended by Herbert,[12] who showed that the drug must be administered early in the infection if the animals are to survive. When given in doses of 800 units daily at the same time as the inoculation with *Past. pestis*, streptomycin provided very good protection, 85% of the animals surviving. When treatment was delayed for one, two, and three days after infection the survival-rates fell to 60, 5, and 0%. Survival-times in the animals that died were significantly prolonged. At the end of the experiment the survivors were reinfected with the same dose of *Past. pestis* to test for immunity. No detectable immunity was observed in the animals given streptomycin at the same time as the infection with plague; in the animals treated one and two days after infection there was respectively moderate immunity (26% survived) and good immunity (86% survived) ɩnger the organism was allowed to develop in the before treatment began, therefore, the greater the ɩuent immunity in the animals surviving.

ction of guineapigs and mice by subcutaneous ation with *Past. pestis* produces an infection closely oling bubonic plague in man; intraperitoneal ation results in a more acute type of infection, ponding more closely to septicæmic plague. ling to Herbert, D. W. Henderson has produced nfections in animals closely resembling pneumonic in man by exposing them to aerosols containing *pestis*. In this type of infection streptomycin was ighly effective. One remarkable feature of streptotherapy in experimental plague is the good results ıed with short periods of treatment; even single produce some effect. Sulphathiazole was also by Herbert to be effective, but it had to be given long periods. If the results of these experiments pplicable to man it seems that if streptomycin is to be effective in human plague it must be given ı a day or so of the onset, or at any rate very

Owing to the relative scarcity and expense of the it is unlikely to be tried on a large scale for eatment of plague yet awhile. At the moment the successful readily obtainable remedy appears to be adiazine, which is superior to the other sulphones for this purpose. This was established by sive field trials carried out in India at Latur and a from 1940 to 1944 under the auspices of the n Research Fund Association.[13]

the basis of experimental work reported by Sokhey Dikshit[14] in these columns in 1940, over 1600 nts were treated with various sulphonamides. The treated with sulphadiazine had the lowest mor-, 21%, compared with 91% in the control cases. value of sulphadiazine in plague has also been onstrated by other workers in India.[15]

FATTY HERNIATION IN LOW BACK PAIN

1944 Copeman and Ackerman[16] reported a series ıses in which low back pain appeared to be due to iation of lobules of what they called "basic fat" ugh the superficial fascia in the region of the iliac s. Such herniations, occurring at weak points, symptomless until made turgid and œdematous g., by injury or confinement to bed—they considered e the cause of a proportion of low back disabilities, a number of patients were relieved by their surgical sion. Herz[17] now reports 37 cases treated in this with satisfactory results. He agrees that the overy of a tender nodule, injection of which with l anæsthetic relieves the pain, is diagnostic, and later severe and long-standing pain ceases after surgical removal of the protrusion.

here are difficulties in the way of accepting this work ıout reservation. In the first place, there is a lack natomical evidence as to the existence of Copeman Ackerman's basic fat pattern. Secondly, as was tioned in the discussion on Herz's paper,[18] subıneous fatty nodules are to be found in over 50% of ons not complaining of backache Thirdly, the mere ıinistration of a general anæsthetic for the removal of ler nodules will also, as Elliott[19] has shown, relieve the ıful reflex foci of muscular spasm found in cases of low k pain and sciatica due to prolapsed intervertebral s. Moreover, these views conflict with those of geons like Burns and Young,[20] who believe that the lapsed disk is the cause of most cases of persistent back pain. This conflict is certainly no reason for dismissing the evidence for fat herniation as a cause of symptoms, but it is essential to have detailed records of the physical and neurological findings in such cases. In one of the two cases Herz[17] mentions in detail, the referred pain in the leg, the hypoalgesia, wasting, and decreased reflexes might be attributed to disk prolapse, and the few months of relief recorded after general anæsthesia for the mass removal of a large quantity of fatty tissue is not conclusive.

TREATMENT OF DISSEMINATED SCLEROSIS

THE pitfalls awaiting those who seek an effective treatment for disseminated sclerosis are now clearly mapped; and in his Humphry Rolleston lectures at the Royal College of Physicians last week Prof. P. C. P. Cloake marked them anew. Despite his caution there seems to be real promise that the treatment which he has practised for the last 17 years is an advance on existing alternatives. Broadly, it is based on repeated courses of T.A.B. pyrotherapy along with alternating courses of intravenous organic arsenic and oral inorganic arsenic. These remedies, as Professor Cloake said, have been used before in disseminated sclerosis; the novelty lies in his insistence that their administration must be continued for at least five if not ten years.

Out of 422 cases observed, 312 have been followed up. Of 64 slight cases that received adequate treatment, 39 are today well, 20 are improved, and 5 are unchanged; none is worse. Among the moderately severe cases, *only 1 is materially worse. It is all too easy*, as Professor Cloake indicated, to draw over-optimistic conclusions from these results; for example, the patient who felt that he was not benefiting from treatment may not have stayed the course, and will thus have been lost to the follow-up. This does not alter the central fact that for all their deficiencies the figures seem better than those obtainable with other forms of treatment.

SCOTTISH REGIONAL BOARDS

CHAIRMEN of the five regional hospital boards for Scotland have now been appointed. They are: Northern region, Mr. Donald Macpherson, convenor of Inverness public-health committee; North-eastern region, Dr. May Baird, convenor of Aberdeen city public-health committee; Eastern region, Mr. William Hughes, treasurer of Dundee corporation; South-eastern region, Dr. J. R. Greenlees, chairman of the Royal Hospital for Sick Children, Edinburgh; and Western region, Prof. E. P. Cathcart, F.R.S., recently retired from the chair of physiology in the University of Glasgow, and formerly chairman of the Scottish Health Services Committee.

THE 17th International Physiological Congress, under the presidency of Sir Henry Dale, O.M., opened at Oxford last Monday. The meeting is being attended by nearly 1200 physiologists representing almost every country in the world except Germany and Japan. The congress has only twice before met in Britain—at Cambridge in 1898 and at Edinburgh in 1923.

THE chief medical officer of the National Coal Board is to be Dr. E. H. CAPEL, of Birmingham. Details of the appointment will be found in our news columns.

Sir ARTHUR RUCKER has been appointed deputy executive secretary of the preparatory commission of the International Refugee Organisation. As deputy secretary to the Ministry of Health since 1940, he has taken a constructive part in the preparations of successive Governments for a National Health Service, and in discussions with representatives of the medical profession. To his new work he brings experience of relief and refugee administration gained in 1941–43 when seconded for special service as secretary to the office of the Minister of State in Cairo. In the preparatory commission his senior will be Mr. William Hallam Tuck, of the United States.

Special Articles

TUBERCULOSIS IN GERMANY

WITHIN the past year tuberculosis in Germany has been the subject of some alarming reports. A recent example is an article in the *Manchester Guardian* of June 4 in which a special correspondent gave disquieting figures for deaths, notifications, and hospital beds. For 1946 he estimated the number of tuberculosis deaths in Germany as 152,000, and the number of cases as 759,000, and he said that the number of beds is inadequate. In an accompanying editorial, the *Manchester Guardian* expressed grave concern. A second article, giving figures for Berlin and the United States zone, appeared on July 14.

The original report, however, based on information obtained from a German source by a non-medical person, must be treated with reserve, and many of its statements do not seem to be compatible with the data published by the British and United States elements of the Control Commission for Germany. These data are based on the official death returns made by German doctors; and, as there is no shortage of doctors in Germany, there is no reason to doubt that death notifications are properly made.

MORTALITY

The deaths from tuberculosis in the British zone during 1946 total 13,673,[1] which for a population of 22,795,000 gives a rate of 60 per 100,000. The tuberculosis deaths in the U.S. zone from March, 1946, to February, 1947, total 9442; this figure is arrived at from the death-rate of 56·6 per 100,000 given for the population of 16,682,000.[2] No figures are available for the French and Soviet zones, but if the rate were the same as that in the British zone, the total would be 12,803 deaths in the population of 21,339,000. Finally if one applies to the whole population of Berlin the rate of 257 found in the U.S. sector of Berlin, one arrives at a total of 8172 deaths from tuberculosis in that city. To summarise:

	Population	*Tuberculosis deaths*	*Tuberculosis death-rate per 100,000*
British zone	22,795,000	13,673	60
U.S. zone..	16,682,000	9442	56·6
French and Soviet zones	21,339,000	12,803	60
Berlin	3,180,000	8172	257
		44,090	

This total of about 44,000, based on official returns, is low compared with the *Manchester Guardian* correspondent's estimate of 152,000; and the following points deserve notice:

1. There is close concordance between the figures for the British and U.S. zones, though the two zones have operated quite separately in the past. This fact in itself makes any gross error unlikely.
2. The total of deaths for Berlin (8172), arrived at by applying to the whole Berlin population the rate found in the U.S. sector of the city, is almost the same as the only official mortality figure quoted by the correspondent (June 28 and July 14). There is no reason to believe that figures for the U.S. zone are any less valid than those for the U.S. sector of Berlin.
3. The great difference between the rate for Berlin and the rates for the British and U.S. zones shows the fallacy of estimating the total deaths in Germany by applying the Berlin rate to the whole country, as the correspondent does in answer to criticism (June 28).
4. Finally, British zone totals for the first quarter of 1947 (not shown above) show no increase over the totals for the first quarter of 1946. Even supposing the zone figures to be fundamentally false in some respect, an absence of increase would still be noteworthy and at variance with the assumption of a continuing 30% rise in deaths year. His estimates are in fact based on this assumption, and he goes so far—proceeding in ge progression—as to predict a total of 440,000 losis deaths in 1950.

CASE-NOTIFICATION

Rises in the number of cases notified in Germany often adduced as evidence of a great increase of culosis. It is now, however, recognised that cation figures are an unreliable index of tub trends. In a press release dated April 10, 1947, R *Martin*, public-health adviser to the Control Com expressed doubts about figures of notified cases: this connexion it should be remembered for what worth that cases diagnosed tuberculous get a mentary ration." He also explained that until autumn statistics referred only to the open case; then all new cases of "active" tuberculosis have notifiable. Mr. Aneurin Bevan, at a recent co pointed out that in England tuberculosis mo falling while notifications are rising, and justly a the latter trend to increasing diagnostic facilities.

MASS MINIATURE RADIOGRAPHY

A Control Commission press release dated June 1947, gives the result of a mass-radiography su 60,000 persons in Hamburg. The number of infectious tuberculosis discovered amounted to 2·9 1000—a figure remarkably similar to figures for populations. The prevalence of known infectious in Hamburg is 3·4 per 1000, and we get therefore a prevalence of infectious cases of 6·3 per 1000. This f for an urban population, belies many alarming rep

TUBERCULOSIS BEDS

The latest 1947 figures for the British zone show 24,295 beds are available and occupied by tubercu cases, while the U.S. zone has 21,045, of which are in tuberculosis hospitals and sanatoria. These represent, in the British and U.S. zones respectively, 177 beds and 223 beds per 100 deaths, compared fewer than 100 beds per 100 deaths in Great Britain only about 20 in Poland. In the light of these figures is a striking fact that, when the Polish staff and tuberculous patients of a Displaced Persons hospital in many were ready for return to Poland, permission for them to take the hospital equipment and bedding with them was refused by the military authorities.

Clearly, so far as tuberculosis is concerned, the interests of the German civilian population are being closely safeguarded by the Control Commission. In General Clay's report for the month of May, quoted by the *Manchester Guardian* correspondent on July 14, concern is expressed because in the U.S. zone only 21,045 beds are a for tuberculosis, leaving without hospital facilities 14, or 40% of all cases of infectious tuberculosis. In this country certainly considerably more than half of infectious cases are not in hospital. It seems likely that the relatively generous *hospital accommodation* in Germany, by isolating the *open case* and preventing spread in conditions manifestly favourable to disease, is partly responsible for the unexpectedly low tuberculosis figures revealed in this analysis. The figures for Berlin remain, and were to be and there must be similar figures for some other towns, but in the zone totals they are tempered by the lower rates in areas where "Berlin conditions" do apply.

CONCLUSION

Apart from a few urban areas, tuberculosis is being well in check in Germany; the death-rates, and morbidity as revealed by mass radiography, are *no* hig than in England.

PURE AND APPLIED CHEMISTRY

CENTENARY AND CONGRESS

)URING the Chemical Society's centenary celebrations London this month Prof. C. N. HINSHELWOOD, F.R.S., ivered a presidential address, which will be printed in ;*Journal of the Chemical Society.* In the course of it said:

" One of the unmistakable trends of the past century s been the successive decline of different aspects of lividualism: the independent craftsman, the aristo-atic politician, the empire-building explorer all departed om the scene. In science a similar trend has been sible though at a lag of several decades. At the time our foundation the stage is dominated by the amateur, iether a Cavendish or a Faraday: later the individual more and more frequently dependent upon the uversity or technical college, small and independent it none the less a community. Then the great research sociations appear and the State subsidy becomes dispensable. Two great wars intensified and acceler-ed the collective process in the world of science until day we are faced with the problems presented by ist industrial research laboratories and by State enter-rises undertaking work which is inconceivable without ie coördinated efforts of hundreds of men of science. he great question is what is to be the fate of the dividual in the world which has emerged. In this atter something of an ideological battle has been igaged. . . . Complete individualism means chaos, hich is only given form by something analogous to an iergy factor—by State compulsion or by powerful notional forces. If any of these controls are applied too igorously the result is order indeed but the order of tter stagnation. . . . Nothing is less fruitful than octrinaire argument about freedom and planning. The ast achievements of military regimentation in war-ime have been cited as examples for peace, but in this is forgotten that the results in limited spheres have ad to be bought with an utter disregard of cost, whether f money, happiness, or life. . . . Those who call them-elves planners are often, I think, not conscious enough f the art and effort involved in large-scale action. t is still the individual who really counts. but his roblems are different. . . . The Faraday of tomorrow ill have by his own methods to break through the rammels of an over-organised society: and for this it nay well be that he will need something of the quality f a Nelson."

International Congress in London

Delegates from 28 countries attended the eleventh nternational congress of pure and applied chemistry, which was opened in London on July 17, immediately fter the Chemical Society's centenary celebrations. The congress, under the presidency of Viscount LEVER-IULME, continued until July 24, and some four hundred papers were read.

LACTATION

MOHAMED EL SHAHAT (Egypt) described a new fat-soluble, thermostable, lactation-promoting factor isolated from the unsaponifiable matter of fenugreek oil; it is not a tocopherol. This " H " factor promoted lactation in 345 out of 350 cases of human lactation deficiency in a dose equivalent to $^1/_6$ mg. by mouth. The volume of milk was increased in 158 cases by 100–900 %, the increase being greatest in the early stages of lactation. The content of fat, proteins, lactose, minerals, and vitamins was also increased.

S. J. FOLLEY and F. G. YOUNG declared that in the cow in declining lactation crude anterior-pituitary extracts have a greater galactopoietic effect than purified prolactin; there is little correlation between the pro-lactin content and the galactopoietic activity of different pituitary extracts. This activity is due to a number of anterior-lobe hormones, two members of which are probably prolactin and adrenocorticotrophin. Substantial and profitable, though temporary, increase can be obtained with cows in declining lactation by injection of crude extracts of ox anterior-pituitary tissue; there is, however, no effect at the peak of lactation. On the other hand, extracts of sheep and pig pituitaries cause a sustained depression in lactation, possibly because of antihormone formation.

IMMUNITY

In a paper on nutrition and disease in early life A. N. WORDEN said that studies on lambs and calves indicate the importance of colostrum in species with a syndesmochorial placenta. They provide also valuable experimental material for the investigation of the influence of nutritional status on antibody production. Owing to the variable resistance of different calves (possibly a breed difference) to colostrum deprivation, it is possible to rear calves that have an incomplete serum-globulin picture, but which are capable of producing antibodies to defined stimuli. Results with calves suggest that the rôle of breast milk (including colostrum) in the human infant's disease resistance might be reinvestigated.

INSECTICIDES

F. P. COYNE said that future competitors would have to achieve an extraordinarily high standard if they are to replace the new insecticides introduced since 1939. More likely developments in the immediate future are: (1) the production of formulations devised for specific purposes, (2) application techniques, and (3) concentration of effort on entomological problems for which the present new group is not particularly effective. Progress will depend on the combined efforts of specialists in universities, research institutions, industrial organisation, and Government departments.

FOOD AND NUTRITION

J. R. MARRACK said that, with continued deliberate selection of food, assessment of the community's well-being would be needed, in order to decide whether the food-supply is well selected, and to satisfy the public that their food is adequate. The tests that may be used are: (1) vital statistics, but people may be below par for a long time without dying, and death-rates are being constantly affected by new remedies such as penicillin; (2) surveys of morbidity, the objection here being that results depend on the subjects' memory; (3) clinical examinations, which are influenced by personal factors and are held to be worthless by those who do not approve of the results; (4) heights and weights of children, which are probably the best criteria; (5) functional tests, the results tending, however, to be influenced by the attitude of the examiner and the examinee; and (6) laboratory tests. These tests should be carried out at regular intervals on representative samples of the population, preferably together with surveys of food eaten.

ANCEL KEYS (U.S.A.) described the Minnesota starvation experiment in which 32 young men were observed during three months of normal nutrition; six months of semi-starvation, during which they lost 24 % of their body-weights; three months of restricted refeeding; and ten months on unlimited diets. Activity approximated the whole time to that in light industry. In rehabilitation the changes in body water and fat obscured the valuation of " active " tissue recovery from gross weight alone. Under the most favourable conditions full recovery required from six to twelve months. Calorie intake was more important, during recovery, than supplementary vitamins and proteins. Intakes of over 4000 calories a day promoted the most rapid weight recovery, but the added weight was mostly fat and there was relative obesity. With very high intakes (over 5000 calories) there was sometimes a tendency to congestive heart-failure.

ANTIBIOTICS

S. A. WAKSMAN (U.S.A.) said that as many as 20–40 % of all cultures of actinomycetes isolated from soils, composts, peats, and dust produce agents inhibiting the growth of bacteria, fungi, or bacteriophages. Of the four genera of actinomycetes—namely, streptomyces, nocardia, micromonospora, and actinomyces—the first is known to produce the greatest number of antibiotics; the nocardia group has so far yielded only two antibiotics—proactinomycin and nocardin. The third has yielded one, and the fourth none. Streptomycin is produced by strains of *S. griseus* and by certain other actinomycetes.

In a joint paper, H. R. V. Arnstein, A. H. Cook, T. H. Farmer, and M. S. Lacey referred to some of the antibiotic solutions obtainable from fusaria and effective in particular against *Mycobacterium phlei*, which is a convenient representative of the acid-fast bacteria.

R. K. Callow reported that *Bacillus licheniformis*, an organism of the *B. subtilis* group, produces material with antibiotic activity against *Mycobacterium phlei*, *M. tuberculosis*, and other bacteria.

INDUSTRIAL TOXICOLOGY

G. R. Cameron, F.R.S., in an address on the toxicity of D.D.T., said that poisoning is heralded by premonitory symptoms and an increase in the white blood-cell count. Its main action is on the central nervous system, and particularly the motor cortex; but it may also damage the liver, and to a lesser extent the kidneys, heart, and voluntary muscles. No genuine evidence of hypersensitisation has been recorded.

R. A. Peters, F.R.S., L. A. Stocken, and R. H. S. Thompson described how Bal, developed at Oxford during the war as an antidote for arsenical war gases, acts by forming ring compounds with trivalent arsenical compounds, so much less dissociable with tissue constituents than the arsenic compounds that the toxic effects of the arsenical can be reversed. Moreover, the injection of Bal in oily solution benefits at least half of the patients with exfoliative dermatitis due to arsenic therapy. Bal has also proved of value in acute mercurial poisoning. Bal-glucoside has been synthesised and shows promise of success in therapy.

DRUGS AND CHEMOTHERAPY

D. Bovet and P. Viaud (France) described the anti-histamine drugs discovered since 1937; although many different chemicals have some anti-histamine action, few possess it to any great extent; but N-*p*-methoxy-benzyl-N-dimethylamino-ethyl-aminopyridine is effective in very small doses.

W. Bradley, in a report on muscle-relaxing drugs of the glycerol series, said that some glycerol ethers inhibit the growth of both gram-positive and gram-negative organisms; many have narcotic properties; others are able to relax skeletal muscle in animals and in man. The most successful compound is α-o-tolyl ether, and a small group of related ethers are also effective, though in smaller degree.

Discussing the effect of ionisation on the activity of sulphonamides A. T. Fuller said that the activities of the sulphonamides, both actual and relative to each other and the antagonising power of *p*-aminobenzoic acid vary greatly with the pH. For example, while sulphabenzamide is only one-twentieth as active as sulphathiazole at pH 7, it is ten times as active as pH 3. Interpretation of results is not easy because the exact degree of ionisation of the compounds is difficult to determine and because the assumption that conditions within the cell are identical with those in the culture medium may not be justified.

P. Ofner, R. H. Thorp, and E. Walton, in a paper on amidone and its analogues, said that synthesis of analgesics based exclusively on the morphine model is unlikely to yield the most fruitful results. The latest synthetic analgesic, amidone, which is highly active, bears only a slight chemical resemblance to morphine. Ofner and his colleagues have recently made a series of ketone analogues of amidone, and are now preparing compounds as closely related as possible to amidone, with the object of discovering whether this drug exhibits peak activity, and of correlating the nature and positions of the groups in the amidone molecule with analgesic activity.

BRITISH MEDICAL ASSOCIATION

THE REPRESENTATIVE MEETING

The annual representative meeting of the
under the chairmanship of Dr. J. B. Miller, of
London last Tuesday. Sir Hugh Lett was
president of the association for the coming year,
Sir Lionel Whitby was elected president for
Dr. J. C. Matthews and Dr. H. W. Pooler were
vice-presidents in appreciation of their excep
services to the association.

NEGOTIATIONS WITH THE MINISTER

Dr. Guy Dain, chairman of council, gave an
of the Negotiating Committee's work since the
representative meeting. The Minister of Health
he said, accepted the committee's position and
agreed that amendment of the Act was a
The Negotiating Committee had set up a series of
committees, covering all aspects of the Act; and
subcommittee had had meetings with a senior
the Ministry. There had been no attempt by
Ministry to limit the scope of discussions.

> "We have spoken to our principles: we have not
> any point to the Government from the position you
> taken up. . . . You will be interested to know that we
> been strengthened in the proper character of our con
> there has been no retreat from any of our principles."

The Act had been thoroughly covered; but there
be a few further meetings to cover one or two
points. The Negotiating Committee was on the
of making a written statement on the discussions,
would be sent to the Minister at the same time that
officers reported to him; this would counter the
that the committee's views might become attenuated
the Ministry officials' report of the proceedings.
Minister would also be asked to meet personally the
sultants and specialists', the general-practitioner, and
public-health subcommittees. When the Minister's
was received, a representative meeting would be called
decide action. Dr. Dain asked for patience and trust
the committee.

Subsequent speakers pressed for an early report on the discussions. Dr. H. H. Goodman (Newcastle-on-Tyne) said that the public was thinking that silence meant consent. The profession was being jockeyed into a position from which there would be no retreat. "I feel that our leaders are only prepared to fight a rearguard action. . . . Are we sitting on the fence, or are we running away, or both?"

Dr. J. E. Purves (Bromley) was sure that the Negotiating Committee would do nothing of which they or the profession would be ashamed; so the whole advantage of secrecy was with the Ministry. Dr. R. W. Cockshut (Hendon) was, however, delighted with the course of events; the Negotiating Committee had, he said, gathered strength in the course of the discussions. It would not be wise, as had been suggested, for the profession to have a showdown with the Minister just when his answer was expected.

Mr. A. Dickson Wright (Marylebone) likened the profession at the present time to an expectant father trying to read into every rattle of a bowl what is going on upstairs.

Mr. A. L. Abel (Marylebone) emphasised that, except on the day that the negotiations began, there had been no discussions with the Minister himself; the discussions had all been with civil servants.

Dr. Dain said that the Negotiating Committee's report, which would be issued as soon as possible, would enable the profession to marshal its forces for the plebiscite that was to be held. He understood the difficulties of protracted secrecy; week-to-week reports by the committee would, however, not have helped since no answers to the committee's arguments had yet
received.

A motion by Newcastle-on-Tyne that the Negot
Committee should be asked to make an early report on
discussions with the Minister was lost.

fter considerable discussion a motion by Dr. R. G. DON (Bath) was amended to read :

> hat in the event of the Negotiating Committee's failing ecure the Minister's agreement to the declared principles, divisions of the association should be asked to meet, in r to instruct their representatives before a special meeting he representative body is held, to discuss the action to taken. Further, that the council should then give a ng lead to the profession in the light of the findings of special representative meeting when issuing the plebiscite ns.

this form the motion was carried.

(To be concluded)

THE MEDICAL PROTECTION SOCIETY

AT an extraordinary meeting of the London and unties Medical Protection Society held on July 16 was resolved that the society's name should be changed The Medical Protection Society Ltd.

Addressing the annual meeting which followed, Sir **NEST ROCK CARLING**, the president, said that the mber of new members rose from 1087 in 1945 to 1894 t year—a record figure. The number of applications advice and help had also risen, from 1040 to 1410. o or three of the cases defended had forcibly illustrated fact that even the most careful doctor may meet th misfortune and be liable to error, leading to the position of heavy damages. Moreover the costs of igation were rising. During the past year he had been uck by the comparative frequency with which the ndible was fractured during extraction of teeth: e fracture was often so slight as to be exceedingly ficult to detect, yet heavy damages might have to be id. It was impossible to emphasise too often the cessity for (*a*) keeping records, and (*b*) informing the tient or his friends if anything goes wrong. Sir nest spoke regretfully of the apparent tendency of dges, in assessing damages, to blame the doctor not erely for any unfortunate consequences of his actions or s failures but also for the entire disability occasioned by e patient's disease or injury.

Dr. **BENTLEY PURCHASE**, commenting on a sentence the annual report, pointed out that the coroner's esire to be promptly informed of cases in which an quest may be necessary is based on the convenience the relatives, not of the coroner himself.

Dr. **JOHN STARTIN**, in view of the comprehensive haracter of the society's new title, hoped that it would enceforth include doctors practising in the United tates of America.—He was informed that the high cost transatlantic litigation would necessitate a much rger subscription if the society became Anglo-American.

Sir Ernest Rock Carling was re-elected president and Mr. . M. Mollison treasurer ; Dr. Thomas Beaton and Mr. F. A. uler were elected vice-presidents ; and Dr. Annis Gillie and r. F. H. Stevenson were elected new members of the council. r. R. W. Durand was re-elected secretary, and tribute was aid to the principals—Dr. Durand, Mr. S. Rayner, and iss K. E. Remington—for a skill and efficiency which are eflected throughout the staff.

The society's office is at Victory House, Leicester quare, London, W.C.1.

COLONIAL STUDENTSHIPS.—The allowances payable to olonial medical research students (*Lancet*, 1947, i, 733) have been amended as follows : at the Universities of Oxford r Cambridge the maximum allowance will be £260 per nnum ; at the University of London, £250 per annum ; nd at other universities in the United Kingdom, £220 per nnum.

A NEW microfilm service has been started by the Pasteur Institute in Paris. On request the institute will issue microfilms of articles in the reviews and journals available. The ervice is offered free of charge to all who require literature on research methods and developments in bacteriology.

Reconstruction

ADMINISTRATIVE RESPONSIBILITIES OF THE MATRON

FROM A CORRESPONDENT

THE 1946 report of the Association of Hospital Matrons includes revised model Standing Orders for the Matron. This attempt by the association to establish the matron in her rightful place in the hospital and thus to remove misconceptions is well timed. The new standing orders represent in many respects a big advance on older versions, which often hark back to the days when the matron was housekeeper rather than professional head of the nursing staff. The new code is shorter and less dogmatic, and free from petty and irritating rules restricting her freedom ; and it is recognised that the question whether the matron should carry the responsibility for catering is one for each hospital to decide. The wording seems to relate primarily to the voluntary hospital organisation, and the comments which follow refer, therefore, mainly to the voluntary hospitals.

A MATTER OF INTERPRETATION

It is no secret that in too many hospitals there is tension between the matron and the house-governor or secretary and his administrative staff ; and many will look carefully at the new standing orders to see whether they offer any help on this vexed question. What they do say calls for some scrutiny. Apart from a passing reference to consultation over the suspension of staff from duty, the only statements are as follows :

(1) The matron shall be appointed by the board of management or equivalent body and be directly responsible to that board.

(3) The matron will present her own written and verbal reports direct to the executive committee at its meetings and be at liberty to bring forward matters pertaining to her departments.

(15) She will report to the chief executive officer any matters outside her province which may be injurious to the interests of the hospital.

(16) It is found to be of great advantage in the coördination of the work of the hospital, if the relevant minutes of the various meetings are sent to the matron.

So far as it goes there is little with which to quarrel ; but does it go far enough ? A whole world of difficulty and potential friction lies wrapped up in that innocent-seeming phrase " and be directly responsible to the board." Its ambiguity may not be at first sight apparent, but quite different interpretations can be placed upon it. It may be taken as an emblem of professional status entitling the matron to deal " direct " with the board and to go over the head of the house-governor to the chairman of the hospital or to the board whenever she chooses. Alternatively, it may be taken by the layman to mean not only that the matron is subordinate to the house-governor qua official representative of the board, but that this subordination extends to her professional duties. (He may, for example, regard the determination of the size of the nursing staff as a matter rather for himself than for the matron.) Both schools of thought have behind them a considerable body of opinion, and the pity of it is that the matrons of tomorrow are being trained in one school and the lay administrators in the other. This is laying up trouble for the future. The divergence is not confined to terminology ; it affects the whole conception of the place and future of the nursing staff in the hospital and the extent to which lay opinion is entitled to intervene or overrule. A professional issue of serious import to the future of the hospital service is involved.

It is a misfortune, therefore, that the new standing orders are not free from ambiguity. Clarity here is important, and an attempt at disentanglement may be opportune.

THE ISSUES

The difficulty arises partly from a failure to distinguish the professional responsibilities of the matron from other responsibilities which may be of a merely administrative character; and partly from a failure to appreciate the fact that direct responsibility to the board does not mean responsibility to the board only when it is in session.

The ultimate responsibility of the board for the conduct of the hospital is discharged in two ways: (*a*) by delegation of care of the patients to the medical, nursing, and other specialist professional staff; and (*b*) by delegation of the authority of the management committee in all administrative matters to the chief executive officer and his staff. This is simple enough; but complication arises because in many hospitals the matron is expected not only to accept professional responsibility for the nursing care of the patients but also to discharge certain other duties as an administrative officer of the hospital, in respect of which she has no special claim to professional privilege. The two spheres are in practice often inextricably tied together. It is not surprising that confusion results and that friction is often generated in the process.

To resolve this confusion three things are necessary. First, the professional status of the matron as chief nursing officer must be fully recognised and defined. In this capacity she is undoubtedly directly responsible to the board. It is a heavy responsibility, analogous to that which rests upon the medical staff. She has no committee to share that responsibility (for at present the nursing committee, where it exists, is almost always a lay body, a subcommittee of the board), and it is fatal to the proper interests of nursing if the matron is liable to be overruled on professional matters by lay opinion.

Secondly, her standing orders should be so framed as to make it clear that she carries also a lay administrative responsibility. There are parts of her work in respect of which no special professional privilege can properly be claimed, and in respect of which she is a member of the administrative staff of the hospital, of which the house-governor is the head.

Thirdly, means must be found of expressing in some formula, as simple as possible, the status of the house-governor and its implications for the matron. His authority flows from the fact that between meetings of the board he acts as its official representative as well as its secretary. His is, like the matron's, a continuing authority, and the position is hopeless if the matron does not recognise this fact. Further, the matron should recognise that even where professional matters are concerned, her proper approach to the board is through ordinary procedure. In good committee practice it is well understood to be essential that members desiring to bring up some matter for discussion should first notify their intention to the secretary; very often they will also seek the opportunity of discussing their project with him, without in any way relinquishing their ultimate right to place the matter on the agenda. So far from regarding it as derogatory to her professional status, the matron should not hesitate to follow a similar practice; and in the interpretation of minutes and other decisions of the Board she ought to accept his opinion pending any necessary clarification by the board itself.

SOME ALTERNATIVES SUGGESTED

How can these things be crystallised into model standing orders? It is not very easy to find wording to fit them into the new model of the Association of Hospital Matrons, since no modification would be adequate which fails to take account of the complicated administrative structure of the hospital. This need seems to dictate something on the following lines:

(*a*) The matron is professionally responsible to the board for the nursing care of the patients and for the supervision of the nursing staff. She will be afforded opportunity to report to the board and its subcommittees on all such professional aspects of her responsibility.

(*b*) The matron may also be required to accept administrative responsibility for other departments of the work of the hospital as may be determined by the board from time to time.

(*c*) The matron's responsibility to the board shall be held to imply collaboration with its chief executive officer, in his capacity as secretary to the board and as its official representative when not itself in session; and she recognise that it is his duty to interpret decisions and intentions of the board.

Since, in practice, professional and administrative matters are closely related, she will keep him fully informed in regard to professional, as well as administrative matters which may be of concern to the board.

If the Association of Hospital Matrons would agree to this, their recommendations would be more likely to prove acceptable. An acceptable formula would be valuable, since there are indications that hospital managements are today only too often led to adopt, *faute de mieux*, an over-simplified lay version of the situation which contains a real threat to the future of nursing.

Medicine and the Law

Yet Another Overdose of Carbachol

FOR the fourth year in succession we record a fatality due to an overdose of carbachol ('Moryl').[1] Once more there is evidence which suggests that the instructions issued by the manufacturers cause confusion.

A doctor, treating a patient for cancer, sought to find accommodation for him in a hospital. He was told that no beds were available, and the resident surgical officer advised him to give the patient an ampoule of carbachol. The doctor, who had never used the drug before, obtained three ampoules from a local chemist, and, having read the instructions, he dissolved the contents of one ampoule and made an injection in the patient's arm. The patient immediately collapsed; he died before any antidote could be given. Giving evidence at the inquest in Worcestershire, the doctor said that the ampoules were not such as he expected. Each was 0·1 gramme while the proper dose was 0·25 milligramme. There was nothing to indicate that they were not for injection. The coroner said that, if the doctor had spent a considerable time reading the instructions down to the last word, he would have discovered that he was administering a dose 400 times too strong. Returning a verdict of accidental death, the jury absolved the doctor and the chemist from blame, but said that greater care should be taken with the instructions inserted in packages of drugs of such a type.

This is not the place in which to assign legal responsibility for the Worcestershire fatality. A pathologist testified that the deceased could in any event hardly have survived six months, and, had he lived, would have been a cause of sorrow to himself and to those who nursed him. But one may emphasise the general seriousness of the position and the evident risk of confusion. The drug is issued in a weak and a strong form. The weak form is for injection in cases of intestinal or vesical atony. The other form, 400 times as strong, is intended for ionisation in rheumatic conditions, &c. If the leaflet instructions inserted in the packages of the strong form can be read as applying to the weak form, tragic results are likely to occur. A practitioner may use the strong form when he believes he is using the weak. So long as this risk remains, the manufacturers should make even more energetic attempts than they have already made to call in every package of the kind which has caused such disastrous confusion. Meanwhile practitioners, chemists, and hospitals must take all possible steps to avert further deaths of this kind.

In England Now

Running Commentary by Peripatetic Correspondents

MALL but elegant, the first post-war exhibition of the lical Art Society, now on view at the Royal Society Iedicine, deserves a better attendance than it was ing on the first afternoon. Leo Spira's smooth and ning ducks, carved in wood, set the note for a group rtists chiefly moved by country sights, whether at ie or abroad. Most memorable perhaps are the pale Indian scenes in water-colour of D. M. Kellett ding, with such unexpected depth and distance veyed in such light tones. In his "Teesta River" still whites and greens build up to a towering landpe like that of an Italian primitive; but the shadowy rway of "Pandrathan, Kashmir" is perhaps even ter. Several painters valued the English climate—A. Pannett in his "March Winds," and Emanuel ler in "Cloudy Weather." The quality of light in the ond had something in common with that of "Avenue Helmieh, Cairo," by G. K. Gillan, whose sun-tired ina had *drained the colour out of yellow and darkened* ens almost to black—an effect achieved in the English ne not by fatigue but by a trick of the stormy skies. Two drawings were particularly telling—the ghostly Vashing Day" of Sir Henry Bashford, where the dim n is barely seen against the tall tenement, and "The spital Ship, Vasna" by E. Puddy, showing a surgical ration at sea. The folds and creases of linen, the nes of table and figures, and the dark heads grouped out the work, must have been a strong invitation to good a draughtsman.

Among several pictures by Henry Wilson, "The oded Thames," in greys and greens, was perhaps standing, and of several bold works by Sir Harold lies, "Cliffs on Blackwater, Ireland" was the most esting. John Parkinson's agreeable "Port in Britny," and T. Holmes Sellors's happy water-colour of ouped trees, after a drawing by Cox, both repay ention. K. Shirley Smith's "Caporetto and Monte ra" showed San Antonio floating on the wave of the en valley, a tiny ark below the transparent mountains. ie or two pictures were *not* well hung, notably one lled the "Evolution of Hearing" by F. Aylmer Hort, ich was beyond the close examination of anyone low middle height.

Portraits were scarce; apart from two uncatalogued tle girls, there was only the fine head of the coloured House Surgeon" by Elliott Blake. A picture of usual charm and humour was "China Horses" by C. Dalzell. Anyone who owns a set of such horses ows well their splendid roundness, their romping itudes, the melting-candle quality of their legs, and limpid yellow-green of their glaze. But Dalzell has ught them to life by blackening their eyes and manes, d setting off their subtle colour against a dim lilac sert and a bluish sky. They are at once alarming and ractive, strange Galateas of a Chinese Pygmalion.

* * *

It is strange that little attention has been paid to cupational hazards confronting the laboratory worker. ue, some mention has been made of such trivial accints as dioxan poisoning, and injuries from acids and her substances, but no-one appears to have described ar more serious condition. This syndrome—provisionly designated microtome sickness (syn. knife apoplexy) is peculiar to laboratory technicians and others sponsible for the welfare of microtome knives. The set is rapid and in severe cases an attack may terminate tally within a few minutes. Non-fatal cases return wly to normal after showing signs of impaired mental lance for days.

Before describing a recent case it is as well to stress r the benefit of the uninitiated that a *good microtome* ife—of the sharp non-section-scoring variety—is lued beyond riches by its owner. It has been truly id that the chastity of his womenfolk is of far less portance to the laboratory worker than the edge of s knife. Good knives are rarely left unguarded for moment, and special precautions—man-traps, barbedre entanglements, chains, and padlocks by the score—have been used in many laboratories to repel the casual borrower.

There is one *really good knife* in our department under the care of a gnarled and aged technician. Recently this worthy retainer chanced upon a lab boy sharpening a pencil with the knife; not *a* knife but *the* knife—bolts and shackles, thunder and lightning—THE knife. Within a moment a severe attack of microtome sickness (syn. knife apoplexy) was upon him. His eyes bulged almost on to his cheeks, his breathing became heavy, involuntary shudders shook his entire frame, the skin became livid, and with a loud agonised shriek he fell to the ground, his hands and fingers making feeble clutching movements in the air. There was a little froth on his lips, and a low moaning sound could be heard. Within an hour he regained more or less full control of his faculties, return to normal being marked by the utterance of bad language and murderous threats. Arrangements have been made to provide safe passage of the lab boy to some far distant shore.

* * *

A certain labour exchange has a scheme for the employment of epileptics, and our lady almoner has referred several patients there at my request. On arrival they seem to have been told in an offhand manner that no employer will take them on. In spite of a certificate indicating what was suitable and what unsuitable employment, one who was eventually given a job found it so unsuitable that he had to leave after two days. Strings have now been pulled and all is well again, but the trouble need never have arisen.

This illustrates well the difference between a plan in *principle* and in *practice*. The scheme was sound in principle, but the administration was appalling. Let us be sure before introducing too many schemes that we have the administrators to carry them out efficiently; and by administrators I do not mean only the heads of departments but the whole chain from top to bottom, for a chain is as strong as its weakest link, whether it be the *first*, *middle*, or *last*.

* * *

In Somerset a cure for warts is to have them bought from you. A young farmer told me how he had sold fifty or more which had grown on the backs of his hands. One evening in the Black Lion a strange man approached him and said he would buy the warts, if my friend was willing to part with them. He protested that he would be only too glad to give them away, but that, it seems, cannot be done with warts, and he had to name a price. So he sold them to the strange man for twopence, and within a week they had vanished.

If this treatment is to be more widely used Mr. Bevan must get moving with the Verrucæ (Treatment of) Bill, 1948, so that (1) the procedure for registration of transactions may be drawn up, with penalties for selling any wart more than once; (2) registered medical practitioners may claim expenses legitimately incurred in buying warts; and (3) a controlled price for warts may be fixed (in consultation with the Board of Trade), and circularised weekly to the medical profession.

Otherwise I can see this valuable remedy falling into disrepute.

* * *

When we had our annual bazaar at St. Malaprop's there were crowds of honoraries roaring in corners; half the residents had crept from their posts to buy sweets off the ration, and everywhere sisters and nurses *billowed starchily* under foot. It was very crowded and airless, and presently a woman fainted at the senior casualty officer's feet. He rushed away in horror; Theatre Sister ducked behind the home produce stall, and Sir Frank Pus became absorbed in a tea-cosy. Just then a man thrust forward importantly: "Stand back," he shouted, "I am a first-aid worker."

* * *

Somebody asked my four-year-old niece if she was going to be a doctor like her mummy and daddy. "My goodness, no," she cried scornfully, "I'm going to be a patient."

* * *

. . . And then there was the fellow who thought a rhesus factor was a man who sold monkeys.

maintained the standard usual for the 2nd M.B.
iinations on structural anatomy, and included
tions on the general lay-out of the central nervous
m, and also questions on embryology. There was also
ree-hour practical examination in histology, which
ded written questions.

mparison of the examination results with those of
last few years in Birmingham shows that we were
ng with an average body of students whose know-
of topographic anatomy, as revealed by examina-
was equivalent to the standard of former 2nd M.B.
ents who had dissected for five terms, and whose
dard in histology was at least equal to that shown
xaminations of the preceding five years. It was,
ever, observed that most students were weak in
r knowledge of embryology, and that the majority
w distinctly more about the central connexions of
nervous system than had been anticipated. In
ral, our view is that the standard of knowledge
topographic anatomy was up to the average of
M.B. students in other medical schools.

e hope to submit a further statement about the
ving of these students in part II of the 2nd M.B.
mination, which will be held at the end of the spring

R,—My fellow-examiners have joined me in a
ement about the results of the recent 2nd M.B.
mination in Birmingham. May I comment briefly
few points raised in your correspondence columns
eply to my article on the changes introduced in the
ningham anatomical curriculum?

he first of our three 10-week terms assigned to
graphic anatomy was devoted, during this past
, to the dissection of the limbs and thorax; the
nd to the abdomen, pelvis, and perineum, and part
he head and neck; and the third to the remainder of
head and neck, and the brain. Professor Green has
gested (April 12) that the load in the *first* term may
e been unduly heavy. This was also our fear, but it
spired that most students held the view that the
od when they dealt with the head and neck consti-
d the heaviest burden. Since the end of the course
have had discussions with the students, and
le we propose adhering to the same time-table in
coming academic year, we shall attempt to simplify
undergraduate's task with "prosections" and
ected specimens. Professor Green also suggests that
course which we have planned would be better
d for a period of six rather than five terms. Both I
my colleagues are in complete agreement with this
which has also received the approval, in principle,
ur medical faculty. Unfortunately, other circum-
es make it impossible at the moment to devote a
term to the study of anatomy and physiology.

Howard-Jones (April 19) points out that questions
orm of the medical curriculum were ventilated well
the publication in 1925 of Abraham Flexner's
of the subject. I was aware of this, and perhaps you,
ill permit me to point out that the original MS.
you received stated that Flexner's book could
convenience" be taken as representing the start
ent discussions. I am grateful to Dr. Howard-Jones
ferring to the many inquiries carried out in this
y beginning in the earlier part of the 19th century.
d it difficult to comment on Professor Le Gros
remarks (May 10), for it would seem that he has
e understood the character of the "reintegration"
e are effecting between anatomy and physiology.
appreciate that the anatomical aspects of a given
may take longer to display, either in practical
or in lectures, than the physiological, and vice
We accepted this fact from the start, and have
gly weighted "anatomy" and "physiology"
separate course of lectures, according to the
nce of the issues discussed. We are not, however,
ed with the question as to whether some particular
s "anatomical" or "physiological." Our main
present to the medical student the anatomical and physiological knowledge of a subject in a single pattern. Professor Le Gros Clark also suggests that it would have been wiser if, in our reintegration, the teaching of physiology had preceded anatomy. This is a speculation on which I prefer not to comment, especially as our aim is to develop the two subjects in their interrelation.

RECONSTRUCTION

SIR,—As one who ventured to criticise your article under the heading of "Reconstruction" on March 15 as coming dangerously near to party politics and as dealing, in your pages, too exclusively with economics, may I congratulate you on the two latest in this series, and especially the article (June 28) over Sir Ronald Davison's signature?

His review of local area and boundary problems is most informative and helpful. But in both his paper and in the latest, that on food-supplies and production (July 12), one of the most important factors in connexion with reconstruction has been omitted—viz., the influence of the height and destination of ground rents. No engineer could start without first ascertaining data on which he must construct his work. One might as well ask someone for the cubic capacity of a cistern and give him only two dimensions as ask anyone to embark upon social reconstruction without taking ground rents into consideration. They affect and are affected materially by subsidies, price controls, taxation, &c., which are frequently referred to; but ground rents are not mentioned by your contributors.

Mundesley, Norfolk.

S. VERE PEARSON.

BRONCHOMEDIASTINAL TUBERCULOSIS

SIR,—The interesting article in your issue of July 5 by Dr. Stevens calls to my mind the following case which I saw in consultation a short time ago.

The patient was a male mongol, aged about 6 years, who had a left axillary swelling, due to enlarged glands, which was of some months' duration and had recently become fluctuant. No other glands were enlarged and the spleen was not palpable. More recently there had appeared a red papular rash confined to the trunk; this was lichenoid tuberculide. There was clinical evidence of meningitis, of which the patient died.

Lichenoid tuberculosis is seen usually in children with glandular tuberculosis, and is due to lodgment of the bacilli in the skin capillaries. It is a recoverable condition. In this case it should have directed attention to an active tuberculosis focus somewhere in the body—most probably in the mediastinal glands as pointed out by Dr. Stevens. With treatment on the lines suggested by him—recumbency in a plaster bed, &c.—acute vascular dissemination and meningitis should have been prevented. Unfortunately radiography of the chest was not practicable, owing to the advanced state of the patient's illness.

Shanakiel, Cork.

J. P. SHEEHAN.

VAGAL RESECTION FOR PEPTIC ULCER

SIR,—In your leader of July 19, after drawing attention to some obvious dangers of the operation, you suggest that vagal resection may prove more than a passing fashion, especially as it is founded on "elegant theoretical considerations." Since many attempts are being made to provide a physiological justification for this operation perhaps you will allow me to indicate briefly some of the reasons which, in my opinion, invalidate the relevant argument and expose the fallacy of its rationale, in the hope that it may damp the enthusiasm of enterprising but undiscerning surgeons.

Dragstedt and Schafer, writing in 1945, justified the introduction of this operation as follows:

> "Acting on the conception that the hypersecretion of gastric juice in gastro duodenal ulcer is very largely neurogenic in origin, a series of patients with this disease have been treated by operation designed to remove permanently and as completely as possible the vagus innervation of the stomach.... The desirability of such a complete operation was indicated by the studies of Hartzell. This investigator found that

the earlier napkin and crawling stage ?—Mr. STRACHEY: is a concession which I would very much like to make.

Working Party on Nursing

Mr. P. PIRATIN asked the Minister of Health when the rking Party Report on Nursing was to be published; d whether the publication would contain the full minority ort.—Mr. A. BEVAN replied: I have not yet received this ort, but I expect to do so in a few days' time.

Public Health

ACUTE POLIOMYELITIS

MORANDUM BY MEDICAL OFFICERS OF THE MINISTRY OF HEALTH

THE notifications of poliomyelitis and polioencephalitis the week ended July 12 numbered 110 and 16. The ghest weekly figure previously recorded since polio-yelitis became notifiable in 1912 was 82 in the week ded August 13, 1938. Bearing in mind the usual asonal trend and the fact that a significant increase in tifications rarely appears until the end of July, the rly start this year and the present high figures are asons for anticipating an unprecedented prevalence.

So far this year the notifications of polioencephalitis ve been higher than ever before. Bulbar and respira-y paralysis and meningeal reactions preceding paralysis pear to be more common than is usual in poliomyelitis.

CLINICAL FEATURES

Typically there are three phases in the illness recognis-le as poliomyelitis. In many cases there is also an tial or prodromal illness followed by a distinct interval 5–7 days before more serious signs of disease appear. e chronology is as follows:

	Usual interval in days from date of infection	*Manifestations*
age A—		
Prodromal illness ...	1–4	.. Fever, weakness, perhaps sore throat or diarrhœa, and occasionally pain in chest or limbs.
age B—		
Phase 1 (onset) ..	7–18 (up to 21)	.. Fever, flushed face, furred tongue, headache, sometimes vomiting, drowsiness, irritability, vague subjective phenomena, increasingly stiff neck, sometimes exaggerated tendon reflexes.
Phase 2 (pre-paralytic or meningitic) ..	10–15	.. Sometimes well-marked intoxication and coma, pain on flexion of neck and spine, tenderness and hyperæsthesia, sometimes nystagmus.
Phase 3 (paralytic) ..	13–18 (up to 35)	.. Hyperæsthesia and weakness of muscle groups going on to flaccid paralysis due to anterior-horn cell lesions; diminution in tendon reflexes. Often the paralysis improves after reaching its height.

e prominent symptoms in all phases of stage B are erable to the central nervous system; they suggest ertain order of progression which may indicate the gress of inflammation within the central nervous tem. There may be intermissions in this progression, 1 one or both of the later phases may not develop.

INFECTIVITY

he disease has been notified from many different tres throughout the country, and from some of these re has been evidence of radial or concentric spread. It is known that nonparalytic cases of the disease are able to transmit it to others who may or may not develop paralysis.[1] This has been confirmed by laboratory investigations, which have also revealed the presence of poliomyelitis virus in healthy contacts. Infectivity is, however, probably greatest during the phases preceding paralysis: in fact the clinical paralytic disease is essentially an infrequent incident occurring among a far larger number of cases aborting in stage A or phase 1 of stage B; but these are none the less infectious.

ACTION BY PRACTITIONER

At this time poliomyelitis should be considered whenever a practitioner is called to see a febrile child (or even an adult) with indeterminate symptoms, particularly if others in the same environment are complaining of the same symptoms, or if there has been within the previous two weeks any other febrile illness (e.g., "influenza" or sore throat of unknown origin) in the patient or his contacts. The patient should be put to bed in a room by himself and examined at every visit until a diagnosis has been made. Careful search should be made for early indications of invasion of the nervous system; in particular the patient should be examined for neck rigidity, which may be elicited by asking him to kiss his knees while sitting up in bed. If the symptoms continue for 24–36 hours without the appearance of signs indicating one or other of the common infections of childhood, the medical officer of health should be informed. There should be no hesitation in reporting a case to the medical officer of health if, with the slightest suggestion of neck rigidity, there have also been psychological disturbances such as fear, bad dreams, disturbance of sleep, drowsiness by day, restlessness by night, and peevishness; these disturbances not uncommonly precede the signs of meningeal invasion. Home isolation at onset and on suspicion is a most useful measure in preventing spread of the disease. Nose and throat discharges and excreta should be disinfected.

A patient who is suspected of poliomyelitis should be kept continuously in bed in a room by himself for not less than one week, having regard to the well-known tendency for the symptoms and fever to subside in two or three days' time and then to recur. Isolation of confirmed cases from other children should continue for three weeks. Contacts should be excluded from school for three weeks after isolation of the patient. Restrictions need not be placed on adults living in an affected household provided they remain well.

It is notoriously difficult to appraise the value of any treatment in poliomyelitis: there is no evidence that convalescent serum given in or after the preparalytic stage has any curative effect. Experience of prophylaxis with gargles and nasal sprays has been disappointing. There is, however, overwhelming evidence that a recent tonsillectomy increases the risk of a child contracting poliomyelitis, particularly of the bulbar type; where poliomyelitis is prevalent operations on the nose and throat should, if possible, be postponed.

ACTION BY MEDICAL OFFICER OF HEALTH

On receiving a notification or learning of suspected cases of poliomyelitis the medical officer of health should proceed on the following lines:

(1) advise all practitioners in the area;
(2) assist in securing suitable accommodation, including isolation, for the patient;
(3) make investigation of the associated circumstances, including a search for missed and abortive cases;
(4) ensure that precautions are taken, on the assumption that the disease is capable of transmission by mild abortive cases;

---

[1] An illness probably due to the same virus, in which the lower motor neurones escape and the signs and symptoms are predominantly those of meningeal and cerebral involvement, is notifiable as polioencephalitis.

Uganda, Tanganyika, and Bukoba. We have also our big contracts with the Argentine, our colonial projects in tropical Africa, and intimate trade relations with Holland, Denmark, and other European countries. Eastern Europe can give us grain and animal feeding-stuffs. And our own exports are up well above the pre-war level. We have in fact the possibility of a plan for regeneration in Europe and Asia in our own hands without help from the American continent. But with the American continent—if the arrangements are made as an equitable bargain, allowing reasonable latitude in trade agreements—we can progress more quickly still.

Nevertheless Lord Addison gave a plain warning of the difficulties: he said that "the world shortage of such important foods as meat, grain, butter, cheese, condensed and dried milk, eggs, oils and fats, sugar, and cocoa is likely to continue for considerably more than two years." That statement sets out the limits within which we have to work.

MEDICUS, M.P.

FROM THE PRESS GALLERY

Permitted Exports of Food

In the House of Commons on July 14 Mr. J. STRACHEY, Minister of Food, said that apart from the difficulty of finding food to buy we now faced the difficulty of finding foreign currency with which to buy it. The Government had therefore decided to allow the export of certain manufactured foods—such as beer, biscuits, and chocolates—which were of high money value in relation to the quantities of foodstuffs they contained. We should aim at selling £10,000,000 worth of these specialties a year. To do this we should have to use about 0·5% of our sugar, about 0·4% of our fats, and a still smaller percentage of our cereals. With the foreign currency which we hoped to receive from these exports we should be able to buy, for example, nearly 500,000 tons of feeding-stuffs, when available.

Postvaccinal Encephalitis

On July 15 Mr. T. DRIBERG raised the case of an infant girl in Essex who was vaccinated at the age of four months and—because the vaccine did not take—a second and third time within seven weeks. The father alleged that on the third occasion she received a double injection. She had previously been healthy, but on the fifth day after this third vaccination she suddenly became ill, was taken to hospital, and was found to be suffering from inflammation of the brain. Some weeks later, when she was returned to her home, she was blind, and now at the age of thirteen months she was still blind, was not developing in any way, and suffered from fits. Recovery was considered impossible.

Mr. Driberg did not presume to attack or defend any medical practice or treatment; but, assuming that vaccination was desirable, was the Minister of Health certain that everything was done in this case in an orderly and hygienic way? Secondly, what were the statistics for postvaccinal encephalitis? The father quoted in one of his letters a statement by an anti-vaccination organisation (which Mr. Driberg found it hard to accept) to the effect that postvaccinal encephalitis killed more infants than did smallpox. The Minister ought to assure the public about this, or if necessary have a more rigorous, and perhaps an unorthodox, inquiry into the whole matter.

Mr. A. BEVAN replied that very thorough investigation had revealed no fault whatever attaching to the doctors concerned, and no departure from normal practice. Further, he must rebut the suggestion that there were two insertions at the same time. There were three insertions over seven weeks, of which the first two were unsuccessful, and the third (from the point of view of inoculation) was successful. That, he understood, was not unusual. He was informed that postvaccinal encephalitis was extremely rare, particularly in infants under one year of age—so rare that it amounted to one in 49,000 inoculations. So parents need not be deterred from having their children vaccinated. He pointed out that when the National Health Service Act came into operation compulsory vaccination would disappear. If this country were entirely immune from infection from abroad, vaccination could probabl done away with entirely; but there had been serious cases of smallpox brought in from abroad, precautions were therefore necessary. It would disastrous if people jumped to the conclusion vaccination does not affect the incidence of small It was very difficult for a layman to intervene in field. They had to rely upon the laws of probab and say that there appeared to be some between the comparative immunity from sm enjoyed by the mass of our population and the immunisation. Certainly that conclusion had a statistical foundation than any deductions reached particular cases.

Colonel M. STODDART-SCOTT, M.D., said the Minist his excellent reply had omitted to say anything the lymph with which this child was vaccinated. Ministry of Health was responsible for its product Had that batch been tested, and was there anyth abnormal about it?—Mr. BEVAN: I understand it has been tested, and that there is no evidence of any abnormality.

QUESTION TIME

Venereal Disease in the Army

Mr. WILSON HARRIS asked the Secretary of State for what was the incidence of venereal disease in the Army in Britain in 1938; what it was in the British in Britain today; and in the British Army of Occup in Germany today.—Mr. F. BELLENGER replied: The rate per 1000 troops in the British Army in Britain during 1938 was 11·7. In 1946 the annual rate per troops in Britain was 32·8 and in the B.A.O.R. 158·6. quarterly rate for the first quarter of 1947 was 5·3 per in Britain, and 30 per 1000 in B.A.O.R. This is lower than for the corresponding quarter of 1946 in but approximately the same in B.A.O.R.

Mr. WILSON HARRIS: Does the right hon. gentl think it right that boys of 18 and 19 should be sent to Germ in the conditions shown to be prevailing there? steps is he taking to avoid this happening?—Mr. BELLE In answer to the first part of the question, I have no opti as long as we have to maintain military occupation Germany. As regards the second part, I am taking all poss steps, and so is the General Officer Commanding out to improve the morale of the troops; but I am bound say that conclusions—and sometimes false conclusions drawn from these figures. In 1938 there was probably recording of cases than there was in 1946, and modern med practice, which treats the case much more quickly th did in 1938, probably accounts in part for the appar higher incidence of cases.

Mr. WILSON HARRIS: Would not the right hon. gentl agree that the figures for 1947 speak for themselves irrespective of 1938?—Mr. BELLENGER: I certainly these figures, and I am taking all steps possible to imp them; but I ask the House not to draw too wide concl from the figures. We are never asked these questions the civilian population.

Bovine Tuberculosis

Mr. A. R. HURD asked the Minister of Agriculture if he now reached agreement with the veterinary profession the National Farmers Union on a national plan for the eradication of bovine tuberculosis; and when he exp that a start would be made.—Mr. T. WILLIAMS repl No. Discussions with farming interests on a plan for lishing attested areas have not yet been concluded. difficult questions are involved and at the moment I say when it will be possible to introduce such a plan. worthy progress in the eradication of bovine tubercu nevertheless already being made under the voluntary culosis (Attested Herds) Scheme which now include over a million cattle.

Extra Soap for Children

Mr. F. W. SKINNARD asked the Minister of Food wh would consider extending the extra soap ration for to children up to the age of two years.—Mr. Str replied: I am afraid that with the present shortage I am unable to adopt this proposal.—Mr. SKINNARD: the Minister aware that mothers find it at least as diff keep their children clean in the early walking stage typhoid, 12; measles (excluding rubella), 9133; umonia (primary or influenzal), 332; cerebrospinal er, 67; poliomyelitis, 110; polioencephalitis, 16; ephalitis lethargica, 2; dysentery, 50; puerperal pyrexia, ; ophthalmia neonatorum, 82. No case of cholera, gue, or typhus was notified during the week.

f the 3 cases of smallpox, 2 were notified at Barnsley, and 1 at enhall, Staffs.

eaths.—In 126 great towns there were no deaths from eric fever or scarlet fever, 2 (0) from diphtheria, 5 (0) m measles, 7 (0) from whooping-cough, 82 (6) from rrhœa and enteritis under two years, and 3 (0) from uenza. The figures in parentheses are those for ndon itself.

he number of stillbirths notified during the week 219 (corresponding to a rate of 23 per thousand al births), including 31 in London.

Obituary

ALEXANDER GAVIN MORISON

M.A., M.D. ABERD., D.P.H.

r. Morison, medical officer of health for Wembley, o died on July 16, was born at Banff in 1893. He nt to school at the Banff and Forfar Academies, and nce to Aberdeen University where he graduated in in 1914. After war service in the R.N.V.R. as a geon sub-lieutenant he returned to Aberdeen to tinue his medical training, and was a member of university hockey team. Qualifying with distinction 1919, he held house-appointments both in Aberdeen London. The last of these was at the National spital, Queen Square; and when he entered general ctice in Shepherd's Bush it was with a special interest neurology. He took the D.P.H. in 1927, and gained rience in the London fever-hospital service before ng the appointment of assistant M.O.H. at Bootle. r he was deputy M.O.H. and port medical officer at stol, where he got great satisfaction from housing k in slum areas.

colleague writes: "Dr. Morison came to the rapidly wing borough of Wembley ten years ago when the idea of public health as a necessary nuisance was ng, and the time was ripe for a leader with exactly gifts to develop the new ideal. This he did with standing success, in spite of the severe handicap of a ke which occurred almost immediately after he took office. It is a great tribute to his courage and tenacity to the wise care and companionship of his wife t he worked unremittingly for ten years without r letting his health interfere with his duties. These e no easy years in a big, expanding borough subjected more than half that time to the stresses of war. other man with less reason might have excused him- but Morison never failed to turn out, day or night, every bombing incident.

The memorial he built was a highly efficient public-lth department with every general practitioner his and friend. Local doctors knew what he was ng and what he wanted them to do. Their problems e made easy and their difficulties swiftly overcome his skilful organisation and by his personal help. ients never found themselves mere cases. They ised at once that, whatever had to be done to safe-rd the public, they remained people whose lives interests Dr. Morison had immediately made his sonal concern.

Morison was a gentle man with great tact and ience. Sympathy was inherent in him: he did not d to turn it on for occasions. No matter how foolish uestion might be, he never showed anything but the rest interest, gave the problem most careful thought, the applicant a wise and courteous answer. The tle hesitancy with which he put forward his views uised a profound and extensive knowledge of his He always managed to give a caller the impression t he had nothing better to do than listen to him, that the caller had done him a kindness by coming. s may not sound like a forceful leader: but the answer o be seen in the results of his work."

Notes and News

ELECTRO-ENCEPHALOGRAPHY

SPONSORED by the Electroencephalographic Society, a three-day international meeting of electro-encephalographers was held at the National Hospital, Queen Square, London, on July 14–16, attended by over 50 representatives from Europe and America. An address by Prof. E. D. Adrian, O.M. (president of the society), was followed by a discussion on E.E.G. technique including electrode material and electrode placements. Dr. H. H. Jasper (president of the American Society of Electroencephalography) said that the recommendations for the performance of apparatus and the placing of electrodes in American practice conformed very closely with those adopted in this country. A committee was formed to examine the possibilities of starting an international journal of electro-encephalography.

Physiological aspects were considered on the second day, with contributions from M. A. B. Brazier (Massachusetts Hospital), H. Gastaut (Marseilles), G. D. Dawson (National Hospital), Prof. J. ten Cate (Holland), and others. Clinical aspects were then discussed, and the meetings concluded with a review, Twenty Years of Clinical Electro-encephalography, opened by Dr. E. A. Carmichael (National Hospital). During the proceedings Dr. Jasper expressed the view that, from what he had seen, Great Britain was in advance of the rest of the world in electro-encephalographic technique.

LABOUR-SAVING IN HOSPITAL

THE Hospital Domestic Aids Exhibition, organised on behalf of the Ministry of Health by the British Electrical Development Association with the coöperation of the British Gas Council, will remain open at the Empire Tea Centre, 22, Regent Street, London, S.W.1, until August 2. Morning sessions are reserved for hospital representatives, but the public are admitted from 1.0 to 5.30 P.M.

In opening the exhibition on July 14, Mr. Aneurin Bevan, Minister of Health, said that hospitals must attract domestic staff of good calibre: systematic training and a proper ladder of promotion to higher domestic posts are desirable. Good welfare arrangements and good tools are also necessary: the "tools" displayed at the exhibition are being produced now, though some waiting may be unavoidable before orders can be fulfilled. "There are signs," Mr. Bevan added, "that the supply of domestic workers is beginning to improve. Over 2500 women from displaced-persons camps in Germany were brought in during the winter and are proving a great help in many hospitals, including sanatoria." Because of the need to free the nurses from domestic work hospitals are being urged to review their arrangements and put their extra demands for domestic workers to the Ministry of Labour.

University of Oxford

The degree of D.SC., honoris causa, is to be conferred on Dr. C. H. Best, F.R.S., professor of physiology and director of the Banting-Best department of medical research, University of Toronto.

Dr. George Gordon has been appointed dean of the medical school for one year from Oct. 1.

University of Edinburgh

Prof. J. R. Learmonth delivered the promotor's address at the graduation held on July 16. The following degrees and diplomas were conferred:

M.D.—Louise F. W. Eickhoff, *R. O. Gillhespy, *L. S. Glass, *Matthew Hunter, †M. S. Jones, *J. M. Kerr, §H. M. King, Samuel Lipetz, *R. M. S. McConaghey, §D. B. Peterkin, §J. A. Ross, J. N. Swanson, G. B. Tait, *E. R. C. Walker, ‡A. W. Wright.

Ph.D. (in the faculty of medicine).—Oscar Olbrich.

M.B., Ch.B.—Margaret Y. Abbey, R. MacG. Aitken, W. S. Allan, Beatrice M. Allen, Marjorie R. Allison, D. W. Anderson, Ernest Armitage, H. S. Bannerman, T. L. Barclay, M. A. Barnor, Mary S. S. Barr, Doris M. Beaton, K. W. Blaikie, Iris M. L. Bowman, R. A. Bremner, Margaret S. Brooks, Elizabeth L. Brown, I. F. Bruce, J. G. S. Buchanan, Anne M. Calder, D. M. Cameron, James Campbell, Mary G. S. Campbell, Sheila H. Cattanach, Roma C. Cessford, Margaret M. Chalmers, J. A. L. Clark, Marianna I. H. Clark, B. H. Colman, Janette G. Cowie, H. P. Croasdale, J. P. Crowdy, Jean M. Dance, Margaret S. Dawe, D. W. Dawson, J. G. Dickson, T. C. Dow, H. A. F. Dudley, Stella P. Eadie, P. N. Edmunds, Emmanuel Evans-Anfom, Peggy Everett, Doreen I. Faley, R. S. C. Fergusson, John Findlater, T. S. Forsyth, Marion G. Foster, Thomas Galla, J. M. Hagen, ‖Eileen V. Haldane, Frank Halliday, D. MacA. Hancock, Emma P. Harrison, Dinah C. Henderson, Elizabeth H. L. Henderson, Irene M. Henry, Patricia M. Hollis, Anthony Hordern, E. O. L. Hoskins, Margaret J. I. Howat, Mary Howson, James Hughes, D. G. Hutchings, Maurice Hyman, C. W. G. Irvine, J. A.

(5) follow up all notified cases throughout the whole period of their illness, to ensure that their treatment is suitable and continuous.

When multiple cases have occurred in a district all crowded assemblies should be discouraged, and as far as possible all gatherings of young children and unnecessary travel should be avoided. Young children should not be allowed to enter any house where there is a case of undiagnosed illness. Contacts should avoid physical strain. School closure is undesirable, except under special circumstances[2]: this advice does not apply to day-nurseries or nursery-schools. As far as possible the normal groupings of the child population should be maintained and sick children removed promptly.

The medical officer of health should also advise his council first as to what can be done to promote early diagnosis during the acute stage, and secondly what arrangements can be made under the local orthopædic scheme to send all children affected, whether slightly or seriously, to an institution equipped to give such special treatment as may be required to prevent avoidable muscular weakness or permanent deformity. In view of the common occurrence of poliomyelitis below the age of 5 years, and bearing in mind the good results of effective treatment and the serious consequences of neglect, it is important that doctors should know of the facilities for orthopædic treatment available through the maternity and child-welfare and school health services. In the course of their routine visits health visitors may hear of suspicious early cases or of children with mild paralyses due to an undetected attack. If the local prevalence assumes epidemic proportions information should be circulated to the public regarding the care to be observed in the event of attack, and the facilities for treatment available in the district.

In view of the fact that the virus is excreted in the fæces and has been found in flies, the possibility of water-borne or other alimentary infection should be kept in mind; but reliable evidence of spread by these means is lacking.

LABORATORY INVESTIGATIONS

In addition to any routine chemical and cytological examinations of cerebrospinal fluid which may be carried out locally for diagnostic purposes, certain examinations are being done at the Central Public Health Laboratory which, although not of direct help in the diagnosis of individual cases, may throw some further light on the epidemiology of the disease. The specimens required for these investigations are: (i) about 5 c.cm. of serum from definite or suspected cases (where possible two specimens should be taken—one in the acute stage and one in the convalescent stage); (ii) cerebrospinal fluid or fresh post-mortem material from cases of doubtful diagnosis—i.e., those cases in which meningeal or encephalitic signs and symptoms predominate. Post-mortem specimens (brain or spinal cord) should be placed in equal parts of glycerin and normal saline. Both the specimens and cerebrospinal fluid must be kept in a refrigerator, and arrangements will be made for collection if the Public Health Laboratory Service is notified.

Specimens should be sent to Dr. F. O. MacCallum, Virus Reference Laboratory, Central Public Health Laboratory, Colindale Avenue, London, N.W.9 (Tel.: Colindale 6041).

Food Poisoning

Among the recent outbreaks of food poisoning have been one at Twyford, near Winchester, and another at Lincoln.

Twyford, Hants.—Sixteen people attended a luncheon party on July 12; within twenty-four hours 15 had developed symptoms suggestive of bacterial food poisoning. Investigation showed that a blancmange had been contaminated with *Salmonella typhi-murium*, which was isolated from the stools of 3 of the patients. D eggs, from home-grown ducks, were used in the pr tion of the blancmange; but bacteriological of excreta and eggs from these ducks has been n Two people who did not eat blancmange have su from similar symptoms. Examination of spe fæces from the residents and domestic staff showed there were several symptomless carriers of *S. murium*, suggesting that the infection was fairly in the household. It is unlikely that one common of infection will be found.

Lincoln.—Of 77 people who dined at a local on July 5, 34 are said to have suffered from poisoning; there was one death. Most of those a became very ill, with vomiting, severe diarrhœa, temperature, intoxication, and sometimes syncope collapse. All became ill within twenty-four hours eating the infected food, and most within a few ho In 17 out of 18 cases whose fæces were sent for examination, *Salmonella typhi-murium* was isolated; and the salami sausage used in the hors-d'œuvre was also found to contain this organism. Six further cases have come to the notice of the medical officer of health; in each there is a connexion with the food at the hotel dur the danger period. It was discovered that one me of the kitchen staff had recently been ill, and a of her fæces proved positive for *S. typhi-murium*; woman was, however, absent from duty be June 30 and July 7. Another member of the who actually handled the sausage, gave a history diarrhœa on July 4 and 5; and his fæces have found to contain *S. typhi-murium*.

Smallpox

No further cases have been reported in England Wales during the week ended July 22.

Willenhall.—The patient removed on July 9 confined to bed from the onset. Contacts are limited members of the household, all of whom are surveillance.

Bilston.—The period of surveillance of contacts now expired without further cases being detected.

Barnsley.—The last patients, both removed on July 11, are suffering from discrete rashes modified by tion seven and nine days before onset. Contacts still under surveillance but the position is not unsatisfactory.

Poliomyelitis

The 110 cases of acute poliomyelitis and 16 of polioencephalitis notified in England and Wales the week ended July 12 were widely scattered in 82 extra-metropolitan sanitary districts and 11 metropolitan boroughs. Outside the administrative county of L multiple cases of poliomyelitis and/or polioence were recorded in Wareham and Purbeck (8), Hought le-Spring (2), Spennymoor (3), Watford (4), Stock (2), Brighton (2), Sutton Coldfield (3), Hull (2), B ford (4), Dewsbury (2), Sheffield (2), Shipley (2), and Spenborough (2).

The main feature in the epidemiology is the multiplicity of foci, with occasional evidence of conc spread, which is particularly obvious in the south-east and south of London. Since July 1, 27 cases have been removed from Lewisham to L.C.C. hospitals, and t total admissions of suspected poliomyelitis and polio-encephalitis to L.C.C. hospitals has been 65; there now 50 cases under treatment in these hospitals.

The number of cases exhibiting predominantly cereb signs and symptoms is still larger than in any previ experience of the disease in this country. The number of cases notified as polioencephalitis (16) is higher th any weekly total previously recorded. The questi whether these cases are due to the same virus as po myelitis or to some other cause is not yet settled, b poliomyelitis is the most probable diagnosis in pati showing a meningeal reaction.

Infectious Disease in England and Wales

WEEK ENDED JULY 12

Notifications.—Smallpox, 3; scarlet fever, 91 whooping-cough, 2000; diphtheria, 181; paratyph

ENICILLIN IN THE PREVENTION OF NFECTION DURING OPERATIONS ON THE BRAIN AND SPINAL CORD *

. B. PENNYBACKER M.D. Edin., F.R.C.S.
MARGARET TAYLOR B.M. Oxfd
Sir HUGH CAIRNS
K.B.E., M.B. Adelaide, F.R.C.S.
n the Department of Surgery, Radcliffe Infirmary, Oxford

HE prevention of infection of operation wounds, ays an important problem in surgery, is one of the ef anxieties of the neurosurgeon. Brain tissue seems overcome bacterial contamination fairly well, but the tricles and large subarachnoid spaces have very *little* stance. After " clean " operations highly pathogenic anisms, such as hæmolytic streptococci and *Staphy-*ccus *aureus* can produce fatal meningitis ; and, as wan (1938) has shown, organisms hitherto regarded saprophytic may set up subacute or chronic meningitis ich may be fatal or may be followed by meningeal lesions and chronic hydrocephalus—the very condition ich operation was usually designed to prevent.

The factors contributing to infection during operation re been described in a previous report from this partment (Cairns 1939). Since that time, wound ections have become less frequent, but have remained serious handicap. We have therefore used local plications of penicillin powder in the wound, and we ort here the results of two years' trial.

METHOD

The Powder.—Calcium penicillin is mixed with non-crocrystalline sulphamezathine to provide 5000 units penicillin per gramme of the mixture. Sulphameza-ine makes a good vehicle. When applied to the ain it does not produce fits as does sulphathiazole. does not cake when autoclaved at 160°C for 1 hour d it mixes well with calcium penicillin, forming a wder of even consistence which flows easily through e insufflator and shows no tendency to deliquesce. erile penicillin-sulphamezathine powder can now be tained from Imperial Chemicals (Pharmaceuticals) d., who state that it may be expected to retain its nicillin in full strength for a year when stored at a mperature not exceeding 15°C. On the rabbit's cortex stological studies showed that it was not as innocuous sulphamezathine alone, but the effects were " rela-rely trivial " (Russell and Beck 1945).

Its Application.—The powder is placed in a sterile ainless-steel insufflator whose inlet tube contains a ter consisting of a glass tube packed with cotton-wool. hen the operation wound is ready to be closed and all eeding has been stopped, the various layers of the wound e frosted with powder—the brain lightly, and the dura, ricranium, and under-surface of the scalp flap more avily. In wounds of the posterior fossa the powder applied to the exposed surface of the cerebellum, to e dura, to the cut surfaces of the suboccipital muscles, id to the subgaleal space. In laminectomy wounds ie external surface of the dura, the muscles, and the bcutaneous fat are liberally dusted.

In 40 operations the amount of powder used was 7–3·0 g. per wound, with an average of 1·4 g. (7000 aits of penicillin) per wound ; but doubtless a small ortion of this remained in the atmosphere and some may ave escaped from the wound before the scalp was ally closed, particularly when there was much bleeding uring this stage. In posterior fossa and laminectomy wounds the amount insufflated was less than in osteoplastic flaps, averaging 0·7–0·8 g.

PENICILLIN CONTENT OF WOUND

In a series of 24 cases of skull defects repaired with tantalum at a military hospital for head injuries the wound was insufflated with 1–2 g. of powder before closure, and fluid was aspirated from the wound 10–48 hours later and assayed by Dr. E. S. Duthie, whose findings are shown in table I. In all cases a partially or completely adequate bacteriostatic concentration was found in the mixed blood and cerebrospinal fluid (C.S.F.) of the wound up to 20 hours after insufflation. At 21–24 hours there were some marked variations, remarkably high values being obtained in some cases. After 24 hours penicillin had disappeared from the wound fluids in most cases. In 2 cases examination of the lumbar C.S.F. within 18 hours of insufflation showed no penicillin.

In a second series, mostly cases of intracranial tumour, examination of the fluid from under the skin of osteoplastic flaps 10–22 hours after insufflation showed a penicillin content ranging from none to 0·48 unit per ml. (table I). The values were smaller and more constant than in the tantalum-plate series. This is probably explained by the fact that in the operations for tumours the powder was everywhere in contact with tissues having a good blood-supply, whereas in the other series the powder was usually in contact with the tantalum plate on one side and avascular scar tissue on the other. In each series, particularly in the tantalum-plate series, excessive accumulation of C.S.F. under the skin flap, or leakage of C.S.F. from the wound or stab drain, at times led to a low value of penicillin in the aspirated fluid.

TABLE I—PENICILLIN CONTENT OF WOUND FLUIDS AFTER INSUFFLATION, AT OPERATION, WITH PENICILLIN-SULPHAMEZATHINE POWDER

Hours after operation	Penicillin content (units/ml.)	
	First series (repair of skull defects)	Second series (intracranial tumours, &c.)
10–15	1·6	0·48
>15–18	1·25	Nil
>18–20	0·02, 0·25, 0·45, 1·2, 1·3	0·02, 0·03, 0·05, 0·06
>20–24	Nil, nil, nil, 0·03, 0·2, 0·2, 0·6, 2·0, 2·0, 3·0	Nil, nil, 0·02, 0·48
>24–30	Nil, nil, nil, 0·04, 0·1	
>30–48	Nil, nil, nil	Nil

Thus, after local insufflation of 1–3 g. of powder, penicillin is usually present in the wound in adequate bacteriostatic concentration for 18 hours. It is probable that the first 24 hours after operation is the most important period in preventing the establishment of infection due to the operation.

REACTION TO THE POWDER

No fits have followed the application of this powder to the brain ; but, as Russell and Beck (1945) did find some reaction in the rabbit's cortex, we have never used more than a light frosting of powder on the brain itself or in tumour cavities. In the head wounds and most of the laminectomy wounds no reaction has been observed, but in lumbar spinal wounds for removal of prolapsed intervertebral disk, where a large surface of muscle is exposed, we have observed a slight excess of exudate and have therefore drained these wounds for 24 hours through a small stab wound to one side of the lower end of the incision. The amount of discharge from the

University of Wales

Sir Ewen Maclean, F.R.C.O.G., and Mr. D. L. Williams, F.R.C.S.E., received the honorary degree of LL.D. at a congregation in Swansea on July 15.

Scottish Conjoint Board

Having passed the final examination the following candidates have been admitted licentiates of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow:

D. K. M. Allison, W. B. Balderston, Mary E. Barton, Robert Black, J. F. Chacko, J. T. N. Cole, John Crow, T. L. C. Dale, William Davidson, Maureen M. Devine, D. C. Drummond, C. G. Duncan, Sheila M. Forsyth, Samson Goldin, S. H. Goodman, D. S. Griffith, G. F. W. Hossack, Matilda Y. D. Hutchison, William Jack, Leonard Kramer, A. J. Laidlaw, D. M. Lyon, K. I. MacLean, Hector McNeill, Blair Mactaggart, Mary A. Mahoney, Alistair Millar, D. L. Moody, Janet Q. Morton, Mary C. Penny, W. R. Plows, Doreen S. Ryan, Doreen R. C. Scorgie, A. W. R. Thom, Norman Weiselberg, Margaret L. Westwater.

St. Thomas's Hospital

The old students' dinner will take place at Church House Restaurant, Great Smith Street, London, S.W.1, on Friday, Oct. 3, at 6.45 for 7.30 P.M., with Mr. C. A. R. Nitch in the chair. The number of places is limited to 250.

Central Mediterranean Force Surgeons

This dining club is to hold its annual dinner at Claridge's Hotel, Brook Street, London, W.1, on Thursday, Sept. 11, at 7.45 P.M. Surgeons and anæsthetists who served with the Central Mediterranean Force are invited to apply for tickets from the secretary, 10, Park Square West, N.W.1.

National Coal Board Appointment

Dr. E. H. Capel has been appointed chief medical officer to the board. In addition, seven divisional medical officers are to be appointed, one to each of the principal coalfields. It is intended that every major colliery shall ultimately have a surgery, staffed by a doctor and a nurse, and that all plans for new pithead baths shall include a medical treatment centre. Some twenty such centres already exist, with a State-registered nurse at each, under a colliery medical-service scheme started by the Ministry of Fuel and Power in 1945. These centres are being taken over by the board.

Dr. Capel, who is 40, trained at the Middlesex Hospital, qualifying in 1929. He became a M.R.C.P. in 1932 and graduated M.D., with distinction, in 1933. For the past ten years he has been industrial medical officer to a Midlands light-engineering concern. He was until recently secretary of the Birmingham group of the Association of Industrial Medical Officers, and is a member of the advisory medical committee of the Industrial Welfare Society.

Diary of the Week

JULY 27 TO AUGUST 2

Monday, 28th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.
3.45 P.M. Dr. M. Kremer: Motor Functions of the C Cortex.
5 P.M. Dr. T. Symington: Phæochromocytoma.

Tuesday, 29th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. F. Wood Jones, F.R.S.: Human My (First lecture.)
5 P.M. Dr. Keith Simpson: Pathology of Sudden Death.
ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
8.30 P.M. *Orthopædics.* Dr. H. H. Kessler: Cineplastic tions. (Members of the sections of *Physical Medi* *Surgery* are invited to attend.)

Wednesday, 30th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Professor Wood Jones: Human Mycology. lecture.)
5 P.M. Dr. G. Popják: Nature of Parenchymatous and Degeneration.
INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray's Inn W.C.1
4.30 P.M. Mr. V. E. Negus: Larynx.

Thursday, 31st

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. W. J. Hamilton: Early Stages of the Ov
5 P.M. Prof. R. Willis: Embryological Principles in Path (First lecture.)
6.15 P.M. Mr. H. W. Rodgers: Late Result of Gunshot W of the Abdomen. (Hunterian lecture.)

Appointments

BOWEN, R. A., M.B. Lond.: asst. administrator of anæsth St. Bartholomew's Hospital, London.
CAPEL, E. H., M.D. Lond., M.R.C.P.: chief M.O., National Coal
GRETTON-WATSON, B. G., M.B. Camb., D.P.H.: deputy M.O.H. deputy school M.O., Dudley.
LENNANE, G. A. Q., M.B. Camb.: Government M.O., Rotor New Zealand.
LOW, W. A., M.C., M.B. Lond., D.A.: director of departmen anæsthetics (part-time), St. Thomas's Hospital, London.
PALMER, W. L., M.B. Durh.: M.O. in Colonial Service, Somaliland.
PATTERSON, A. S., M.B. Belf.: medical superintendent of colony for mental defectives in Worcestershire under Midlands Joint Board for the Mentally Defective.
WATSON, R. H., M.B. N.U.I., D.P.H.: asst. county M.O. and M.O., Somerset.

Births, Marriages, and Deaths

BIRTHS

ABRAHAM.—On July 14, in London, the wife of Dr. A. John Abraham—a daughter.
CAUSEY.—On July 14, at Carlyon Bay, Cornwall, the wife of Gilbert Causey, F.R.C.S.—a daughter.
HAMILTON-TURNER.—On July 16, in London, the wife of Dr. C Hamilton-Turner—a son.
HARRIS.—On July 11, in London, the wife of Dr. D. V. Har a son.
LLOYD.—On July 10, at Enfield, Middlesex, the wife of Dr. Ken Newton Lloyd—a son.
McCULLAGH.—On July 5, at Cambridge, the wife of Dr. C McCullagh—a son.
MORLEY.—On July 15, in London, the wife of Wing-Comm George Morley, O.B.E., F.R.C.S.—a daughter.
PEMBLETON.—On July 11, at Chelmsford, the wife of Dr. J. Pembleton—a daughter.
PERCEVAL.—On July 14, in London, the wife of Dr. P. E. Perc a daughter.

MARRIAGES

MURRAY—GALWEY.—On July 14, at Hythe, J. G. P. Murray, to Helena Patricia Galwey.
OSMOND—JAMES.—On July 12, in London, Arthur Harold Os to Betty Gwendolen James.
REED—MACKOVER.—On July 14, at Zaria, Nigeria, R. I. L. Reed Freda Susanne Mackover, M.B.

DEATHS

COMERFORD.—On July 15, Beaumont Harry Comerford, M.B. D.P.H.
DRURY.—On July 11, in Grahamstown, South Africa, Ed Guy Dru Drury, M.D. Lond., D.P.H., aged 75.
WILSON.—On July 16, in London, Maurice Ulick Wilson, M.C., M.R aged 57.
WOODRUFF.—On July 14, at Surbiton, David Winthrop Wood L.R.C.P.E., aged 62.

A tablet given by his widow in memory of the Sir Hubert Bond, F.R.C.P., has been erected in the chape Long Grove Hospital, Epsom. The tablet will be unv by Sir Allen Daley during evensong on July 27. The se begins at 5.30 P.M.

ion of gloves despite the fact that this shortened eir life. On two occasions gram-negative organisms re found in the solutions used for irrigation of the erative field and supplied by manufacturers as sterile. 1940, at the time of casualties from Dunkirk, many them with open purulent wounds, we had an epidemic wound infection and meningitis due to *Staph. aureus*, d investigation showed that there had been a tem- rary breakdown in the arrangements for sterilisation linen. The disastrous effect of this breakdown is en in table IV, which shows the incidence of infections years. During the latter part of this first period lphanilamide powder was applied locally to the wound. part from an unusually bad year in 1940, due to the itbreak described above, and an unusually good year 1941, there was in each year a steady incidence of infection in every 20–30 cases, despite the fact that ery effort was made to improve the surgical technique.

TABLE IV—INFECTIONS AT OPERATION (BY YEARS)

Total	670	6	6	0

DISCUSSION

Other methods of chemotherapeutic prophylaxis gainst wound infection at operation are available, cluding the systemic use of sulphonamides or penicillin, id intrathecal penicillin, either before or during opera- on. We believe that, in the absence of pre-existent fection in any part of the patient's body, these methods volve unnecessary trouble to all concerned—patient, irses, and doctors. If calcium penicillin is not available, dium penicillin in solution could be applied locally; ut in most cases a considerable part of it would probably scape from the wound before it was closed. Le Beau ersonal communication) mixes sodium-penicillin solu- on into a paste with sulphonamides at the operating- ble for local application.

Penicillin-sulphamezathine powder applied to the rain as a light frosting has proved harmless in our hands. However, the possibility of contamination of the powder with unsusceptible organisms should always be borne in mind. The insufflator should be charged with no more than a day's supply of powder, and should be resterilised daily; and the air passing into it should be filtered as described.

The antibacterial action of the powder is evidently not sustained for more than 12–18 hours, but it operates at a time when any contaminating organisms are in small numbers. From the delayed onset of suppuration in two of our cases, in one after a second operation and in the other after X-ray treatment, it seems likely that in some cases infection did develop in spite of application

TABLE III—ANALYSIS OF 51 CASES OF WOUND INFECTION AFTER NEUROSURGICAL OPERATIONS

Type of operation	May, 1938–November, 1944						December, 1944–March, 1947					
	Total cases	Infection			Outcome		Total cases	Infection			Outcome	
		No. of cases	Type	Organism	Recovered	Died		No. of cases	Type	Organism	Recovered	Died

drainage hole has been small, and there is no escape of C.S.F., since these operations are entirely extradural.

CLINICAL TRIAL

We began using the penicillin-sulphamezathine powder in November, 1944. With several operators and many different types of neurosurgical operation it was impracticable to establish controls. It was therefore decided to use the powder in every major operation and to compare the results over a long period with those of the previous 6½ years. The results are summarised in table II.

TABLE II—INCIDENCE OF POSTOPERATIVE INFECTION IN "CLEAN" MAJOR CEREBRAL AND SPINAL OPERATIONS

Treatment	Total operations	Infected	Fatal infections
A. No local penicillin (May, 1938–Nov., 1944)	1169	51	13
B. Local penicillin-sulphamezathine (Dec., 1944–March, 1947)	670	6	None

The infections included obvious suppuration in any layer of the wound, obvious meningitis, and cases of pleocytosis of more than 500 white cells per c.mm. in the C.S.F. after operation (table III). With the pleocytosis there was usually headache, fever, and bulging of the region of operation.

Some explanation is required for including these cases of pleocytosis among the infective complications, since Finlayson and Penfield (1941) have concluded that the condition is due to chemical irritation of the meninges by blood products and term it "acute postoperative aseptic leptomeningitis." In 7 of their 19 cases examined bacteriologically bacteria were found in the C.S.F. or in the wound, but they discount these because the organisms were "of a type ordinarily considered non-pathogenic"—e.g., diphtheroids—and careful bacteriological examination (no details are given) showed no "known pathogens." Cowan (1938) had previously shown that certain organisms hitherto regarded as harmless to man, including an organism of the diphtheroid type, *Diplococcus mucosus*, &c., could produce serious postoperative meningitis.

In our cases there was no essential clinical difference between those in which organisms were found (and included in the meningitis group) and those in which cultures were sterile. Bacteriological search was usually not sufficiently thorough to exclude with certainty "non-pathogens." Further, after the introduction of penicillin-sulphamezathine powder the incidence of pleocytosis fell, as did that of proved bacterial infection. The question obviously requires more detailed bacteriological examination on the lines of Cowan's work. Meanwhile on the evidence available we consider that most cases of pleocytosis should be regarded as infective in origin. Some, however, may be due to other causes.

During the pre-penicillin period we had one case of fatal ependymitis of the lateral and third ventricles, after transventricular removal of a fibroblastoma of the septum lucidum; it was due to strands of cotton-wool embedded in the ventricular wall. These had been shed from the strips of 'Lintine' used to pack off the ventricle during removal of the tumour. A similar case has been described in the United States.

A few of the infections may have been due to introduction of bacteria after operation, but most were undoubtedly due to contamination at operation.

In the pre-penicillin period there were 51 postoperative infections in 1169 cases (4·4%). No organisms were isolated in 21 of the 51 infections (16 cases of pleocytosis of C.S.F., 3 cases of scalp infection, 1 fatal case of meningitis after a spinal operation, and 1 case of cellulitis after operation for spinal meningocele in an infant). In the remaining 30 infections *Staph. aureus* was isolated in 20 cases, *Staph. albus* in 3, β-hæmolytic streptococcus in 2, and there was 1 infection with each of the following organisms—streptococcus (unclassified), Friedlander's bacillus, diphtheroids, *B. aerogenes*, and *Ps. pyocyanea* (table III). The incidence of infections in fossa operations was 1 in 12, in operations cerebral hemispheres 1 in 30, and in spinal 1 in 40.

In 1944–47, when penicillin-sulphamezathine was used routinely, the incidence of operative was 6 in 670 (*0·9%*), in contrast with an 4·4% in the pre-penicillin period (table II).

Of the 6 cases of operative infection in the (table III) one was an achromobacter meningitis after of an acoustic tumour; this patient recovered after illness in which he was given vigorous chemotherapy, intraventricular streptomycin (Cairns et al. 1946,

Another was a case of *Staph. aureus* meningitis removal of cerebellar hæmangioblastoma; the developed a stitch abscess on the 11th post followed by a cerebrospinal fistula through the area, and then by meningitis; he recovered intrathecal penicillin.

In a third patient *Staph. aureus* meningitis after a *decompression was probably due to residual infection* occipital muscles, from an operation three months at which an extracranial aneurysmal varix had been.

A fourth patient developed a small *Staph. au* abscess, without serious symptoms, after biopsy of a frontoparietal glioma; this man was prone to *Staph. aureus* infection, for at a previous *his neck wounds for cerebral angiography had* and at the time of his craniotomy he had numerous on the skin of his trunk, and his blood-transfusion suppurated.

The fifth patient developed mild cellulitis of the following X-ray treatment, seven weeks after removal of a temporal glioma; this may not have *to infection at operation, but we think the case sh* included because the third case suggests that, when powder is used, infection with *Staph. aureus* may take at operation without producing overt signs unless the is later disturbed, as by a second operation or X-ray t

The sixth case developed *Strep. viridans* septicæmia removal of a right temporal cholesteatoma. The wound healed normally, but there was a mild p which persisted three or four weeks before it and the cæmia cleared. No organisms were seen in or from the C.S.F., but in view of the septicæmia it is to assume that the meningeal reaction was due to infe We have some evidence that these cholesteatomas of brain may contain organisms, which may explain the ably high frequency *of infection following operation* in cases.

The absence of deaths from infections in the penic period cannot be attributed to the prophylactic u penicillin-sulphamezathine powder, for 2 of the 6 would probably have died without penicillin *of their postoperative infection, and a third* might died without streptomycin treatment. However, tables II and III show, the incidence of infection operation has been significantly reduced since introduction of penicillin-sulphamezathine powder.

CONDITIONS OF OPERATION

Throughout the two periods—i.e., from 1938 to 1947 all the operations were done in the same o theatre, which was supplied with warmed wa filtered air by a 'Plenum' system. 'Cellophane' (Blatt and Dale 1933) and clean theatre footwear worn by all except the patient, and traffic within theatre was always minimal. However, conditions sterility were far from constant. At one time plenum system was unsatisfactory and the air in operating-theatre showed a heavy bacterial count potential pathogens. On several occasions patho organisms appeared in the noses and throats of of the operating staff. As the war went on the and quality of rubber gloves diminished. Because the occasional presence of staphylococcal carriers, on evidence gathered from our gloves and hands Prof. G. S. Wilson, we changed from wet to dry st nisms of the gas-gangrene group are symbiotic and aless in the living muscle of dogs and cats, but when tissue dies they proliferate and liberate their exo- ns (Aub 1944a and b, Haxton 1944, Prinzmetal et al.). Consequently the later stages of many of the riments in which muscle masses were severely matised or isolated from their blood-supply were ies of an overwhelming gas infection and not of ock. Where such experiments were repeated in the sence of sufficient sulphonamide to prevent infection, ny of the characteristic signs of shock did not develop, cept when relatively enormous quantities, amounting nost to a fifth of the total muscle bulk, were isolated m their blood-supply and placed in the peritoneal vity (Fowler 1944). Since comparable injuries are tremely rare in man, it is very doubtful whether the dings of these experiments have any bearing on hock" in the patient admitted to hospital after a road ident.

E II—CHANGES IN HÆMOGLOBIN CONTENT OF BLOOD IN EARLY POSTOPERATIVE PERIOD

Operation	Hb at end of operation (% of normal)	Interval (hours)	Hb after interval (% of normal)	Alteration

Total hæmoglobin change ..				−37
Mean hæmoglobin change ..				−3 7

led 11 hours after operation; pulse-rate increased steadily and blood-pressure fell until death.

ied of hypothalamic disturbance 12½ hours after operation.

led 36 hours after operation with symptoms of left-sided cardiac failure, ashen grey colour, rapid pulse, pulmonary œdema.

the time of taking the second specimens all the patients were pale; the venous blood when removed was unduly dark, indicating a slowed peripheral circulation.

Though our ideas about experimental shock are once re in the melting-pot, the investigations already ntioned (Stewart and Warner 1945, Beecher and rnett 1944, Evans et al. 1944, Cournand et al. 1943) ve gone far to give us some real insight into the signi- ance of traumatic shock in man. Also the circulatory turbances associated with burns have been greatly rified by the Medical Research Council (1944). Post- erative shock, though the commonest variety, has not eived the attention which is its due, and it is with s type that the present paper is concerned.

METHODS

Venous blood was withdrawn after minimal stasis m patients before, during, and after operation. The moglobin content was estimated after Van Slyke et al. 45) from the blood and plasma specific gravities, ich were determined either by Van Slyke's copper- lphate method or the falling-drop method (Barbour d Hamilton 1926), the latter being exclusively used en capillary blood was being studied. It was assumed at the plasma-protein contents of venous and capillary od were identical. Final blood volumes were estimated m the alteration in hæmoglobin produced by the pid injection of a pint of plasma (Bushby et al. 1940). e preoperative blood volume was assumed to be ml. per lb. of body-weight. A 3 : 2 mixture of potassium d ammonium oxalates was used as an anticoagulant, and the necessary correction in the blood and plasma specific gravities was made.

RESULTS

There was no significant alteration in the hæmoglobin content during major operations (table I), nor was hæmoconcentration in evidence in a series of 26 cases where the amount of hæmoglobin was determined only postoperatively—cf. the results of Underhill et al. (1923), Scudder (1940), and Gordon (1945) in burn shock in man. Some patients were followed for some hours after operation, and none of them showed any tendency to hæmoconcentration in this period (table II). Gross rise in the capillary red-cell count was a feature of shock in the war of 1914–18 (Cannon et al. 1919); in the present study the capillary and venous blood hæmoglobin content was therefore determined in 11 patients manifesting greater or less degrees of shock after major thoracic operations; as in the study of air-raid casualties (Kekwick et al. 1941) the mean difference was negligible. The blood volume at the end of some operations was sharply reduced (table III), but the unaltered hæmoglobin levels indicated that the patients were suffering from loss of whole blood in quantity sufficient to explain their shock. It therefore seems that in these patients, who constitute a fair cross-section of the population of a surgical hospital, shock was not due to extravascular plasma loss from either local or general increase in capillary permeability.

DISCUSSION

It may be argued that in the above cases hæmodilution resulting from hæmorrhage cancelled any tendency to hæmoconcentration from shock (cf. Moon 1942). Even if this were true, the conclusion stated in the last paragraph still holds, for the steady hæmoglobin concentration indicates that the patients studied were adding enough fluid to their circulating volume to make good any loss through abnormally permeable capillaries. Extravascular plasma loss will not, therefore, account for the fatal progressive circulatory failure which appeared in two patients, nor for the syndrome of pallor, contracted veins, and dark venous blood manifested by most patients.

TABLE III—VOLUME OF CIRCULATING BLOOD AT THE END OF SOME MAJOR SURGICAL OPERATIONS

Case no.	Operation	Hb. (% of normal)		Blood-pressure (mm. Hg)		Blood volume (litres)		Deficit (litres)	% deficit
		Initial	Final	Initial	Final	Initial	Final

* This patient received a pint of blood and a pint of plasma, a grossly inadequate replacement, and died, about 4 hours after operation, of further hæmorrhage from the splenic pedicle.

Initial blood volumes were calculated on the basis of a normal of 40 ml. per lb. of body-weight. In case 56 the initial blood volume is that before the accident.

of the powder, but was of such low intensity that it would have been overcome without any signs, had there been no further interference with the field of operation. In a previous investigation on infections at operation it was found that bacteria could be isolated from the fluid accumulating in the wound after operation without any obvious signs of suppuration (Cairns 1939).

The powder probably gives no more than slight assistance to the body in overcoming wound infection. It will not do away with all infection at operation, and it is clear that penicillin in full doses by all routes will not prevent intense infections after operations at which severe contamination with virulent *Staph. aureus* has taken place (Cairns 1947). All the usual aseptic precautions against infection at operation should therefore be scrupulously maintained, and indeed improved. In our own operative technique we recognise the need for more regular tests of the efficiency of the numerous measures used to eliminate bacterial infection. The use of penicillin-sulphamezathine powder is an additional measure which appears to be valuable in brain and spinal operations and may prove valuable in other fields of surgery.

SUMMARY

Penicillin-sulphamezathine powder 5000 units per g. was applied locally to cerebral and spinal operation wounds in amounts of 0·7–3 g. as a prophylactic against infection. No ill effects were observed.

Fluids in the wound usually contained more than 0·02 unit of penicillin per ml. up to 18 hours after the powder had been applied. The penicillin was in greater concentration and persisted longer in wounds containing much scar tissue (from old missile wounds of the head) than in fresh wounds with normally vascularised surfaces.

In 1169 consecutive major cerebral and spinal operations before the use of local penicillin there were 51 cases of postoperative infection (*4·4%*). In 670 consecutive major cerebral and spinal operations with local application of penicillin there were 6 cases of postoperative infection (*0·9%*).

The local application of penicillin-sulphamezathine powder is a useful additional method of preventing bacterial infection at operations, but does not do away with the need for continuous supervision and improvement of aseptic surgical technique.

The bacteriological work in connexion with these investigations was undertaken by Prof. G. S. Wilson, Dr. E. S. Duthie, and Mr. R. L. Vollum, D.PHIL., to whom we wish to express our thanks.

"... The birth of a baby in many poorer families—even when they have been fully assessed for the medical costs of the confinement—must mean that the family budget can only be balanced by borrowing or drawing on savings. It has been said that children are 'the chief cause of poverty,' and . . . the drain of family expenditure begins sharply at the birth of the first child. The various forms of assistance to mothers, such as maternity grants and prenatal allowances for servicemen's wives, go only a little way towards reimbursing this expenditure. The major outlay, especially in the poorer groups is made in buying essential clothes and equipment rather than in paying medical and institutional fees. The possibility of bringing about substantial reductions in the costs of childbirth, therefore, depends more on producing cheaper baby clothes, prams and other equipment than on lowering further the cost of medical care."—From a report by a joint committee of the ROYAL COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS and the POPULATION INVESTIGATION COMMITTEE. *Population Studies*, 1947, 1, 1.

MANCHESTER ROYAL INFIRMARY

FEW surgical problems have had so much atte as the ætiology of traumatic shock; but, because of great variations in the human response to injury, and lack of any satisfactory method of measuring the se of shock, the experimental approach has been used al exclusively. Unfortunately confirmation of labo findings by observations on humans has not been so as assiduously as it might have been, and many s misconceptions have arisen.

At the beginning of the war of 1939–45 one school of thought held that shock was the result of extrava loss of plasma through the walls of abnormally perme capillaries, though it was not clear whether the pl left the circulation only in the injured area (Bla 1930, 1931) *or throughout the vascular system* (M 1942). When, however, studies were made on sol wounded in battle (Beecher and Burnett 1944, St and Warner 1945), on civilian victims of road an industrial accidents (Cournand et al. 1943, Evans et 1944) and of air-raid injuries (Kekwick et al. 1941, Gr and Reeve 1941), it was found that they were suffer primarily from loss of whole blood. There was no eviden whatever of plasma loss through the walls of abnormally permeable capillaries, except where it was clear th gross inflammatory exudation was occurring somewhe in the body. Such a process explains the hæmoconcen tration found in burns (Medical Research Council 194 in peritonitis following perforation of a viscus (Scudd 1940), and in the early stages of gas-gangrene (Stew and Warner 1945).

Recently there has come to light a serious source of error in studies on experimental shock. It appears th

Mean Hb change $= +\frac{22}{23} =$ *ca.* $+1$ %.

cause of the appearance of neck stiffness, his cerebro- al fluid (c.s.f.) was examined, and meningitis due to *influenzæ*, Pittman type B, was diagnosed. Penicillin given intrathecally, and the c.s.f. became sterile, the perature normal, and the baby was apparently cured; there was a relapse. Further intrathecal penicillin was ted; but the c.s.f. still contained *H. influenzæ* after six tions of 30,000 units, so it was discontinued. The further s of intrathecal and intramuscular penicillin and oral hadiazine in the doses given did not control the infection, the infant died on June 9.

ermission for necropsy was not obtained. Sensitivity s using 10 units of penicillin per c.cm. showed the organisms e insensitive.

otal dosage : intrathecal penicillin 550,000 units; intra- cular penicillin 4,740,000 units; sulphadiazine 125 g. . 1).

n the light of later knowledge, the relapses in case 1 e due to reinfection of the meninges from bacteræmia, ich was not controlled owing to inadequate intra- scular penicillin. It is possible that intensive ramuscular as well as intrathecal penicillin and l sulphadiazine, as in case 2, would have led to overy.

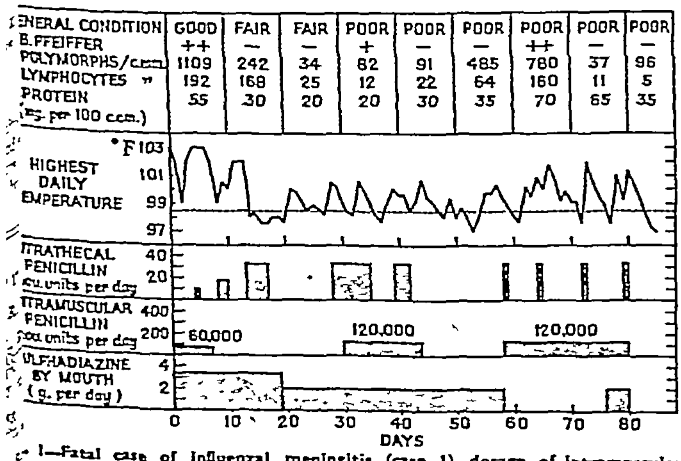
ase 2.—A girl, aged 19 months, was admitted on August 5, 6, after ten days' weakness, vomiting, and slight neck fness. Meningitis due to *H. influenzæ*, Pittman type B, diagnosed. The organism was reported insensitive to icillin and sulphadiazine.

ather empirically, she was given two intrathecal injections penicillin and oral sulphadiazine, but she continued to go nhill. Then, since her condition was so critical, it was ught justifiable to try massive doses of penicillin. She given ten intrathecal injections, each of 50,000 units of e crystalline penicillin, and 960,000 units of penicillin ramuscularly daily (120,000 units three-hourly). After r days there was a striking improvement, and after two eks she was afebrile, the c.s.f. was sterile, and she was ying with her toys. The dramatic change was maintained h complete recovery, and the patient was discharged on t. 26.

Total dosage : intrathecal penicillin 535,000 units; intra- scular penicillin 47,670,000 units; sulphadiazine 65 g. . 2).

In view of the bacteriological reports that the organisms re insensitive to 10 units of penicillin per c.cm., and mg. of sulphadiazine per 100 c.cm., intrathecal nicillin was discontinued, with the gradual deteriora- n of her condition. After receiving massive doses intrathecal and intramuscular penicillin the child overed.

ase 3.—A girl, aged 10 months, was admitted on Oct. 2, 6, after a day's illness, with a convulsion and vomiting. e neck was slightly rigid, and the left drum was red and gested. The c.s.f. grew *H. influenzæ*, Pittman type B.



1—Fatal case of influenzal meningitis (case 1), dosage of intramuscular penicillin being inadequate.

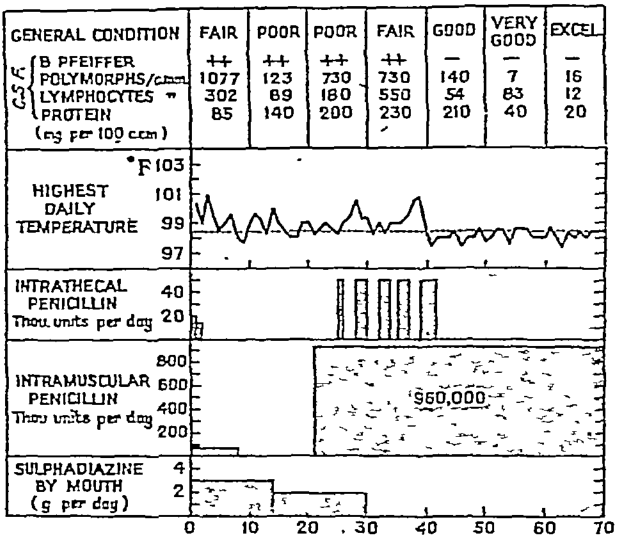


Fig. 2—Chart of case 2, showing effect of massive doses of penicillin in influenzal meningitis.

Owing to our previous experience, intensive parenteral penicillin therapy, with sulphadiazine by mouth as a possible synergist, and intrathecal injections of pure crystalline penicillin were started immediately. Three hours after the ninth intrathecal injection the baby had convulsions and cerebral irritability, and remained pale, shocked, and unconscious for six hours. No more intrathecal penicillin was given. Thereafter, she continued to recover, was perfectly well two weeks after the onset of the illness, and was discharged on Oct. 26.

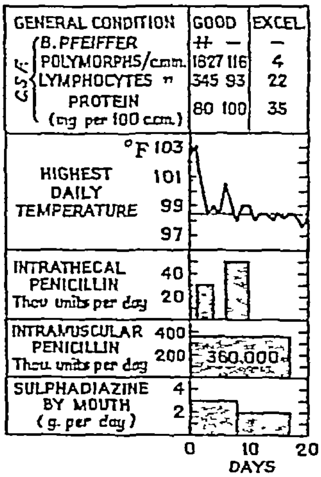

Fig. 3—Chart of case 3.

Total dosage : intrathecal penicillin 350,000 units; intramuscular penicillin 5,760,000 units; sulphadiazine 39 g. (fig. 3).

Despite the bacteriological reports that these organisms were insensitive to 10 units of penicillin per c.cm. and 10 mg. of sulphadiazine and sulphathiazole per 100 c.cm., intensive therapy was instituted with intramuscular and intrathecal penicillin and oral sulphadiazine. Later, the treatment was fully justified when it was reported that the organisms were sensitive to 100 units of penicillin per c.cm.

Case 4.—A girl, aged 23 months, was admitted on Jan. 8, 1947, with three days' history of fever and nausea and a day's history of cough. She had signs of bronchopneumonia involving both lungs, and meningitis with strabismus. The c.s.f. contained *H. influenzæ*, Pittman type B.

Treated with intrathecal and intramuscular penicillin and with sulphamezathine by mouth, she rapidly improved. On Jan. 17 the c.s.f. appeared clear and contained 61 polymorphs per c.mm. The intrathecal injections were then stopped. On the 19th she relapsed, and eight more intrathecal injections of pure crystalline penicillin were given. On the 27th the c.s.f. was clear and contained only 2 cells per c.mm.; so the intrathecal injections were again discontinued. She relapsed, however, again on the 30th, and seven more daily intrathecal injections of pure crystalline penicillin were given; she made an uninterrupted recovery this time and was discharged on Feb. 27.

H. INFLUENZÆ MENINGITIS WITH RECOVERY

REPORT OF A CASE

JOHN GERRARD
B.M. Oxfd

RESIDENT MEDICAL OFFICER, KING EDWARD VII MEMORIAL CHILDREN'S HOSPITAL, BIRMINGHAM

EVERAL cases of meningitis due to *H. influenzæ* ted with penicillin have already been reported in tain (Forgacs et al. 1945, McIntosh and Drysdale 1945, sdale et al. 1946), and Zinnemann (1946) has lately iewed the British and American reports, adding 13 her cases.

n addition to sulphadiazine and systemic penicillin, present case received a solution of pure crystalline icillin intrathecally, with striking freedom from e-effects.

n Oct. 26, 1946, a girl, aged 15 months, was admitted to King Edward VII Memorial Children's Hospital under care of Dr. A. V. Neale. She was the youngest of five dren, all of whom had catarrhal infections at the time. wo days before admission she vomited twice and became table. The day before admission she had a rigor, her neck a little stiff, and she failed to recognise her mother. nig's sign at this time was negative. She was given 0·5 g. a sulphonamide by mouth, repeated after four hours and owed by 0·25 g. four-hourly.

n admission she was flushed and irritable but well rished, with a purulent nasal discharge. Temperature 8°F, pulse-rate 132, respirations 25 per min. Fontanelle but not bulging; throat injected; ears, heart, lungs, abdomen clinically normal; neck not notably stiff; nig's sign negative, but Brudzinski's sign positive; knee ankle jerks present and equal on the two sides; abdominal lexes present; plantar responses flexor.

Lumbar puncture produced a turbid fluid under increased essure, containing 2600 polymorphs per c.mm.; no sugar; otein 50 mg. and chlorides 670 mg. per 100 c.cm. Penicillin, ,000 units, was introduced into the subarachnoid space by e lumbar route.

Microscopy of the cerebrospinal fluid (c.s.f.) revealed many am negative bacilli, which culture proved to be *H. influenzæ*, sitive to both penicillin and sulphadiazine. The organism s not typed according to Pittman's classification (Pittman 31, 1933).

White-cell count (blood): 9500 per c.mm. (neutrophil poly-rphs 20%, monocytes 3%, eosinophils 2%, lymphocytes %).

Treatment consisted of sulphadiazine by mouth, and nicillin intramuscularly, intrathecally, and intracisternally. itially, all the penicillin used was "impure," containing only 50 units per mg. The dosage of intramuscular penicillin s 10,000 units three-hourly, increased after forty-eight urs to 30,000 units three-hourly; and of sulphadiazine 5 g., followed by 1 g. six-hourly for twenty-four hours and ereafter 0·75 g. six-hourly, subject to increase or decrease necessary to maintain an average blood-sulphadiazine rel of 15 mg. per 100 c.cm.

ogress

The initial improvement was dramatic. Two days after mission, the fifth day of the illness, the child was alert, took interest in her surroundings, and recognised her parents r the first time since admission. Her temperature fell to °F, and the c.s.f. contained only 4 cells per c.mm., with organisms, and was sterile on culture.

Next day, the sixth day of the illness, the c.s.f. cell-count se to 97 per c.mm., and penicillin 20,000 units was therefore troduced into the subarachnoid space by the lumbar route. his process was repeated daily for four days, by which time dry tap was obtained.

It was hoped that the meningeal infection had been over-me, but the temperature did not settle. On the twelfth day the illness there was again clinical evidence of meningeal itation, and two days later a solitary gram-negative bacillus as seen on microscopy of the c.s.f.

At this juncture an unsuccessful attempt to obtain strepto-ycin was made. However, crystalline sodium penicillin (prepared by Glaxo Laboratories) became available, and with this "pure" penicillin it was hoped that the "gumming up" of the lumbar subarachnoid space might be avoided. This preparation contained 1650 units per mg.

On the sixteenth day of the illness Prof. F. A. R. Stammers performed a cisternal puncture under general anæsthesia, withdrawing about 10 c.cm. of turbid freely flowing fluid and introducing 40,000 units of the pure penicillin. After this a burr hole was made in order to introduce penicillin into the right lateral ventricle, but the ventricle could not be located.

Two days later daily cisternal punctures under local anæsthesia were initiated, and on each occasion 40,000 units of pure penicillin was introduced after the withdrawal of 5–10 c.cm. of c.s.f., which always flowed freely. Except on two occasions, when the child vomited immediately after the cisternal puncture, no untoward effects appeared: even on these two occasions, having vomited, the child sat up and played cheerfully.

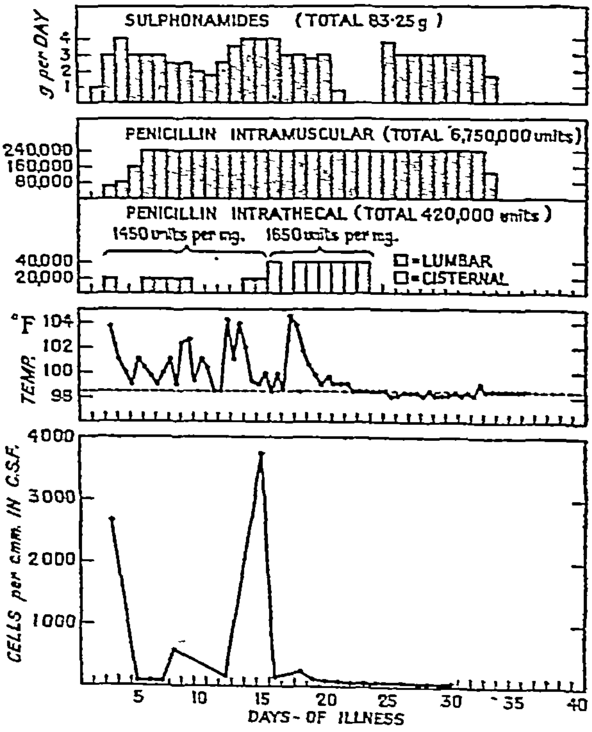
After seven days the introduction of penicillin into the subarachnoid space was discontinued. Further progress was uneventful. The child was discharged on Dec. 3, thirty-four days after admission, bright and cheerful, with no evidence of cerebral impairment.

Her subsequent progress at home has been satisfactory. When last seen, on Jan 21, 1947, there was no evidence of any residual lesion. (For additional details of treatment and progress see figure.)

DISCUSSION

The intrathecal use of penicillin has not yet been standardised. Complications with large dosage, such as "gumming up" of the lumbar subarachnoid space (Smith et al. 1946) and convulsions following the introduction of penicillin directly into the lateral ventricles (Johnson and Walker 1945), have hitherto necessitated the use of penicillin both in comparatively small dosage and by two or more routes in the course of treatment—e.g., directly into the lateral ventricles and/or into the cisterna magna besides the lumbar route—in those types of meningitis which do not respond readily, if at all, to systemic penicillin and/or sulphonamides.

In the present case the patient tolerated the daily introduction of 40,000 units of pure penicillin into the cisterna magna with no complications other than a small



Treatment, temperature, and C.S.F. cytology.

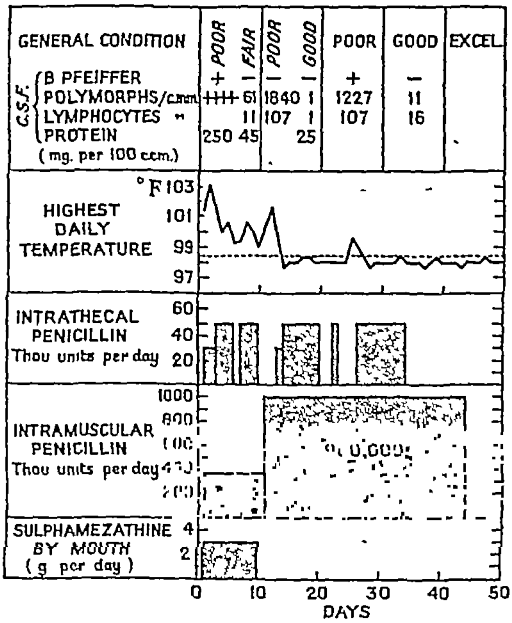


Fig. 4—Chart of case 4.

Total dosage : intrathecal penicillin 1,040,000 units ; intramuscular penicillin 33,430,000 units ; sulphamezathine 24 g. (fig. 4).

This case confirms the necessity for enormous doses of penicillin, and emphasises the importance of continuing the daily intrathecal injections for at least seven days after the C.S.F. has become sterile. It also shows the necessity for the same large doses of penicillin when a relapse occurs. Finally, it demonstrates the relative safety of these large intrathecal doses of pure crystalline penicillin, when administered carefully under strictly aseptic precautions, in a strength of 10,000 units of pure penicillin per c.cm., each dose being made up separately in a sealed glass ampoule.

NOTE ON BACTERIOLOGY (E. N. ALLOTT)

The organisms isolated in all four cases were typical *H. influenzæ* and were all identified by Dr. E. A. Straker as belonging to Pittman type B.

The routine testing of penicillin sensitivity in this laboratory is carried out by the punched-plate method, one drop of penicillin solution, 10 units per ml., being dropped into the punch-hole. By this technique the strains from cases 1 and 2 were found to be penicillin-insensitive. They were also resistant to 10 mg./100 ml. of sulphathiazole and sulphadiazine.

In view of the satisfactory response of cases 1 and 2 to penicillin therapy, the organisms from cases 3 and 4 were tested against higher concentrations of penicillin. With the same technique, but with three concentrations of 10, 100, and 1000 units/ml., the strain from case 3 gave no inhibition, 6 mm., and 15 mm. zones respectively with the three concentrations, whereas that from case 4 gave respectively 5 mm., 9 mm., and 14 mm. We have consistently found that with a concentration of 10 units/ml. the Oxford staphylococcus shows a zone of 12 mm.

It is impossible from these observations to give an exact figure for the concentration of penicillin required for inhibition of *H. influenzæ*, but it is probably more than 10 and less than 100 times as much as that which inhibits the staphylococcus. It is obvious that the strains from cases 3 and 4 differed in sensitivity considerably, that from case 4 being very much more sensitive than that from case 3.

From this work it is clearly unjustifiable to say that an organism is insensitive to penicillin merely from the results obtained on a punched plate with 10 penicillin per ml. Much higher concentrations penicillin must also be tested.

DISCUSSION

The clinical features of *H. influenzæ* meningitis those of the other types of pyogenic meningitis, diagnosis can only be made by bacteriological tion. Most of the cases reported were of the type B, which shows a variable sensitivity to amides and penicillin. Ideally, sulphonamides, and *anti-influenzal serum should* be simultaneously, and Paterson (1946) reported the cure of 2 such cases. We could not obtain the serum, but we found the following régime ment to be successful in the 3 infants so further case treated on these lines in the Brook under the supervision of Dr. J. V. A medical superintendent, also recovered.

Régime of Treatment in Infants

(1) As soon as pyogenic meningitis was diagnosed, units of pure crystalline penicillin was given daily, and 60,000 units of penicillin was given in three-hourly to combat the bacteræmia which is so in influenzal meningitis (Neter, in 1942, noted in 11 out of 17 cases examined).

(2) Sulphadiazine 1 g. as an initial dose, 0·5 g. four-hourly, under the age of two years. given because of a possible synergic effect (Bigger

(3) When the diagnosis of influenzal meningitis was firmed, and the organisms were found to be penicillin in vitro, the treatment recommended by et al. (1946) for pneumococcal meningitis was given.

(4) If the organisms were relatively insensitive, units of pure crystalline penicillin was given daily thecally for at least seven days after the C.S.F. became and 120,000 units three-hourly intramuscularly at the time.

(5) Intramuscular penicillin and sulphadiazine by were continued for two weeks after the C.S.F. became A reduced dose of sulphadiazine was given in the second

(6) The same intrathecal doses of penicillin were for a relapse.

Reactions to the large intrathecal doses of are rare. McIntosh and Drysdale (1945) reported attack with convulsive movements lasting six following treatment with 50,000 units of penicillin thecally on one occasion. We noted a similar lasting six hours after treatment with 50,000 unit pure crystalline penicillin on one occasion only. C.S.F. during the attack showed no obvious If such a reaction occurs, a reduced dose of peni preferably from a different batch, should be given

SUMMARY

Four cases of meningitis in infants, due to *H. influenzæ* relatively insensitive by in-vitro test penicillin, are reported ; three of these cases to massive doses of penicillin.

A régime of treatment found to be effective in is described.

It is suggested that before an organism is reporte insensitive to penicillin in vitro much higher conc tions than 10 units/ml. must be tried.

Our thanks are due to Dr. B. A. Young, medical tendent of St. Alfege's Hospital, for his coöperation encouragement.

n admission : no abnormal physical signs.

igmoidoscopy showed redundant mucosa with blood and cus exudate; granular friable mucosa, extending 10 cm. the rectum; perfectly normal appearance above this area.

crapings: pus cells, macrophage cells, and red cells; *E. histolytica* or ova seen.

lood-count: no leucocytosis and otherwise normal.

ost-dysenteric granular proctitis was diagnosed and ated as in case 1.

roctoscopy a week later showed a rapidly healing mucosa l granular and easily injured.

atient was then discharged but had to be readmitted two eks later owing to a return of symptoms.

Proctoscopy on readmission revealed a friable mucosa with mall triangular area of ulceration $1^1/_2$ in. from the external incter.

Scrapings: polymorphs, red cells, and *E. histolytica* getative forms.

A course of E.B.I. capsules and chiniofon retention enemas s started immediately.

After ten days proctoscopy showed granular mucosa with n-point hæmorrhages and pus, and stools contained red cells d polymorphs as before.

The condition was therefore still regarded as one of granular st-dysenteric proctitis.

Treatment with succinyl-sulphathiazole suppositories was stituted as in case 1, and, a week later, proctoscopy disclosed healed mucosa with no purulent or hæmorrhagic areas. rapings showed red cells only.

Patient was discharged with a supply of suppositories, and wrote on June 22 that his symptoms had completely abated ter the diligent use of the suppositories for a month.

Case 3.—A man, aged 41, had undergone hæmorrhoid- tomy in 1945 after an acute attack of diarrhœa with blood d mucus in the stools.

On discharge from hospital in Persia his symptoms had been ry much worse than when he had been admitted. He had en told that he had "inflamed skin tags" and that he ould improve with perseverance and a little ointment.

Each day, after a bowel action, he had noted blood, slime, ad pus on his stool. There had been a good deal of pain and nesmus, and constitutional signs had been more marked than n cases 1 and 2.

On returning to England he had had "excessive granula- tions scraped and cauterised." Nevertheless the discharge ad continued, and he had had much pain and tenesmus.

Another operation had been performed for the removal of sinus, and he had been relieved of much of his pain, but not f his discharge.

On admission, on June 17, 1946, his general condition was atisfactory, with no abnormal physical signs. Blood-count nd barium enema revealed no abnormality.

Sigmoidoscopy showed a reddened granular mucosa with onspicuous superficial pitting. Pin-points of pus and blood ere situated in this area about 5 cm. from the external phincter. Above this the mucosa appeared normal. The area escribed was very friable and bled on sigmoidoscopy.

Scrapings: red cells, pus cells, and gram-negative rganisms; no *E. histolytica*. Cultures grew *Bact. coli*.

There was also an eczematous condition (œdema with xudate of lymph) of the anal canal and circumanal skin. t some time sulphathiazole powder had been insufflated to lleviate his condition. Since this had been followed by an mmediate exacerbation of symptoms, with marked increase n pain and onset of irritation, the eczema was thought to be n allergic reaction to sulphathiazole, probably aggravated y the continuous discharge from the area of granular proctitis.

A palliative drying paste ('Siccolam') was applied to the eeping area of circumanal skin and in the anal canal, and course of parenteral penicillin 100,000 units three-hourly as started in an effort to clear the rectal infection. In all, $3^1/_2$ mega units of penicillin was given.

Six days later a report on the fæces indicated that pus and blood-cells were still present, and proctoscopy disclosed little or no improvement.

It was decided to use succinyl-sulphathiazole suppositories as in the previous cases while continuing to counteract the circumanal eczema with the bland paste. No allergic manifes- tations followed the use of succinyl sulphathiazole.

Proctoscopy a week later revealed a rapidly healing mucosa with vascular striæ now visible, and no pus or mucus. Mucosa still friable, and bled easily if injured. No pus or mucus on fæces, and only a few red cells present.

On discharge from hospital patient was in relative comfort compared with his original state, and he was instructed to use the suppositories as indicated above. Œdema and weeping of circumanal skin much less after use of siccolam paste.

DISCUSSION

Though the ætiology differed in all three cases, the final result was granular proctitis. Diagnosis was established purely on the sigmoidoscopic findings, excluding lesions proximal to the rectum. Appearances conform to those described by Milligan (1933), who has stated that "In the granular form of proctocolitis the appearance of the rectum or colon when viewed through the proctoscope or sigmoidoscope is granular, vivid pink, and moist. It bleeds easily with trauma and the normal branched blood-vessels are no longer visible. Shallow pitting may be present but deep ulceration of the mucous membrane is absent. Discharge on the surface varies from a trace of blood to large quantities of pus, muco-pus, and blood." Milligan takes great pains to distinguish between the granular and ulcerative forms, constitutional signs being much more severe in the ulcerative form. This is confirmed by our cases where there were very mild constitutional signs in spite of the large quantities of pus voided.

Hardy (1945) stated that "when blood, mucus, and pus are associated with the passage of constipated stools, the disease is usually limited to the rectosigmoid area." Our cases illustrate this point quite well, except that in no instance did the sigmoid appear to be involved.

Hitherto granular proctitis has been most resistant to treatment; the multiplicity of therapeutic agents prescribed is a certain indication of the inadequacy of each.

Manson-Bahr (1943) has had some success with 'Protargol' suppositories coupled with eusol lavage and protein-shock therapy in a case of granular proctitis of gonococcal origin. He has also recommended sulphaguanidine enemas 7–10 g. in 7 fluid oz. of water suspended in mucilage or gum acacia. Nicotinic acid 150 mg. daily is regarded as being of value in the relief of toxic symptoms.

He further states that other workers have claimed good results from bismuth subgallate, suspended in olive oil, as a retention enema.

Autohæmotherapy, protein-shock treatment, and silver-nitrate, silver-albuminate, and tannic-acid gr. 3 suppositories have had their advocates.

Lockhart-Mummery (1934) is of the opinion that electric cataphoresis in selected cases is of value; he describes several cures.

I have not been able to find any references to sulphonamide suppositories in British medical literature, but Howard (1945) in America has recorded the use of "intrarectal powdered sulphonamides in aspecific recto-colitis."

Sufficient time has not yet elapsed in the present cases for an accurate estimate to be made of the value of succinyl-sulphathiazole suppositories; but the symptoms and signs have greatly diminished, and preliminary results appear to indicate that this is by far the best and most economic method of applying sulphonamides to the diseased rectal mucosa. The suppository must necessarily come into intimate contact with it and can remain so for twenty-four hours. Sulphonamide retention enemas can at best exert but a temporary effect. Further, the patient need not be kept in hospital after the diagnosis has been established, if the suppositories become the accepted form of treatment.

PREPARATION OF SUCCINYL-SULPHATHIAZOLE SUPPOSITORIES

(R. H. BARCLAY, M.P.S.)

The recipe for each suppository at the Albert Dock Hospital was:

Succinyl sulphathiazole 3 g.
Cocoa butter 7 g.

vomit on two occasions. There were no convulsions, nor was there ever any evidence, with this preparation, of a block developing in the subarachnoid space. In four subsequent cases of non-meningococcal meningitis treated at this hospital, 40,000–80,000 units of pure penicillin has been introduced into the subarachnoid space daily by the lumbar route without causing cerebral irritation or hindering the flow of C.S.F. This is a happy improvement on the results obtained with less pure preparations of penicillin. It is therefore felt that the use of crystalline penicillin will facilitate the treatment of meningeal infections. Dr. A. L. P. Peeney (personal communication) has found that penicillin introduced into the lumbar subarachnoid space will reach the ventricles within 30 min. when no intervening block is present; a longer time is required to obtain the maximal concentration of penicillin in the ventricles.

It is hoped that the lack of local reaction to the introduction of pure penicillin into the lumbar subarachnoid space will enable a greater proportion of patients to be treated without recourse to cisternal and/or ventricular punctures, for the introduction of penicillin into the cisterna magna, when the patient is uncoöperative and has neck rigidity with head retraction, is more dangerous than its introduction by the lumbar route. Experience, however, may prove it advantageous to introduce penicillin initially more centrally. Gaisford (1946) believes that the intrathecal introduction of penicillin in non-traumatic meningitis is a retrograde step, and that sufficient concentrations of penicillin can be obtained by its systemic use alone. In the present case the patient received 240,000 units of penicillin intramuscularly daily and yet relapsed. It is therefore considered necessary to give penicillin locally as well as systemically where the causal organism is not the meningococcus but is sensitive to penicillin in therapeutic concentrations.

Streptomycin may possibly take the place of penicillin in the treatment of meningitis due to *H. influenzæ* (Birmingham et al. 1946, Nussbaum et al. 1946), but Alexander (1946) reports that *H. influenzæ* may rapidly develop a high degree of resistance to streptomycin. In such cases penicillin will still be utilised. Moreover, severe reactions with the preparations of streptomycin now obtainable are, according to Cairns et al. (1946), not uncommon, though the purer preparations are reported (Madigan et al. 1947) to be less toxic.

I wish to thank Dr. A. V. Neale for permission to publish this case; Prof. F. A. R. Stammers, Drs. E. C. Allibone, A. L. P. Peeney, W. Cant, and H. Baar for their help and advice; and Sir Leonard Parsons for his criticisms.

"... Before individual output can rise significantly we have to repair the loss of that neighbourliness and loyalty which flourished so magnificently in the war and withered so quickly in the peace. This loss touches the human spirit and is not to be made good by clever planning; nor by inducements at the expense of the man next door; nor by threats of direction of labour. ... We are all to blame for this decay of friendliness."—Mr. DAVID ECCLES, M.P., in a letter to the *Times*, July 29.

GRANULAR PROCTITIS
TREATED WITH SUCCINYL-SULPHATHIAZ
SUPPOSITORIES

ERNEST H. CLUER
M.R.C.S.
LATE RESIDENT MEDICAL OFFICER, ALBERT DOCK H
LONDON

GRANULAR proctitis occurs as a late complic
or concurrently with, dysentery affecting the
bowel. It has to be distinguished from chronic
dysentery, chronic intestinal amœbiasis, mucous
and low-grade chronic idiopathic ulcerative colitis
following cases illustrate the symptoms and
course of the condition.

Case 1.—A man, aged 44, while in Palestine fifteen
earlier, had an attack of acute dysentery, with severe
tutional illness. This had cleared after treatment
sulphaguanidine tablets, but looseness of stools p
with passage of blood and slime at end of defæcation.

Amœbiasis had been diagnosed and treated with
injections, emetine bismuth iodide (E.B.I.) capsules
chiniofon pills. Diarrhœa and discharge had ceased.

Four months before admission to hospital he had re
to England and had a relapse of blood and muco-pus in
no diarrhœa, but stools semi-solid.

On admission to hospital on Jan. 21, 1946: no a
physical signs on general examination; but sigmoid
showed reddened friable granular mucosa, extending
into rectum. Mucus and pus on surface only. No ulcer
Mucosa above this area perfectly normal.

Scrapings examined microscopically showed pus
macrophage cells, and red cells. No *Entamœba hi*
seen. Cultures on MacConkey media produced *Bact. col*

Blood-count revealed no leucocytosis and was within
limits.

Post-dysenteric granular proctitis was diagnosed,
course of succinyl-sulphathiazole tablets 6 g. daily was s
together with a retention enema of succinyl sulphat
6 g. to 3 fluid oz. of mucilage daily.

Ten days later proctoscopy revealed a granular bl
area 2 in. from the external sphincter. Appearance of n
suggested little improvement otherwise. Patient's sym
persisted.

It was suggested that succinyl sulphathiazole mig
incorporated in a suppository so that the active sulphon
could be brought into intimate contact with the gr
and purulent areas without the waste involved in ret
enemas. The formula and method of preparation as d
by Mr. Barclay, the hospital pharmacist, are given below.

One suppository was inserted each night well insi
anal canal and retained at least twelve hours. The oral ad
tration of succinyl sulphathiazole was continued as
Ten days later, proctoscopy showed a slightly granul
rather plicated mucosa, which bled easily if injured,
mucus or pus was seen.

Report on stools: well-formed stool; a few red cell

Patient remained well throughout treatment and
discharged with a supply of suppositories, being inst
to insert one on alternate nights for a month. He a
regularly each month to report progress.

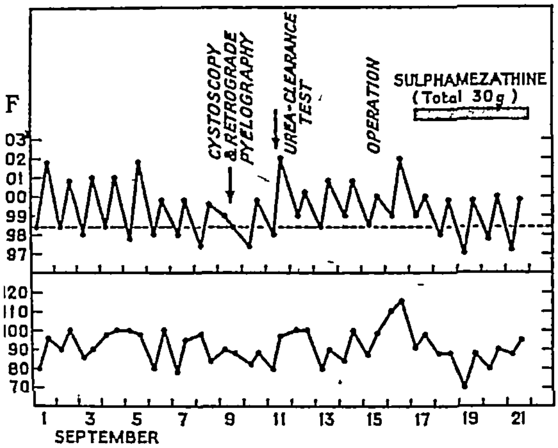
He has remained without symptoms five months
repeated stool investigations give no further evidence of
mucus, or pus.

Case 2.—A man, aged 32, had noted blood and sli
the stool after defæcation when in Persia two years
Fæces had been solid and of normal colour and consis
He had been investigated but not treated.

Fifteen months before admission to hospital he had
in Normandy, two attacks of diarrhœa at an interval of
days, each attack lasting two days, with blood and
in stools, and moderate illness. Treated with sulphagua
tablets the condition had cleared.

Sigmoidoscopy after treatment had led to diagno
amœbic dysentery, *E. histolytica* cysts having been
He had been treated with emetine injections, E.B.I. cap
and chiniofon enemas.

For the last three months until admission to hospit
had had persistent blood and muco-pus on a well-formed
after defæcation. There was no loss of weight and no il



emperature chart of case 1, showing persistent pyrexia before operation.

ited veins, and on cross-section it appeared to be fairly
l encapsulated. The central portion was necrotic. Micro-
py showed the typical appearances of a hypernephroma.
ecovery was delayed by a mild basal collapse of right
g; but, when this cleared, patient's temperature fell and
nained stationary (see figure). His mentality, which had
ome increasingly deranged until the operation, was
tored to normal immediately afterwards, and he remained
ite sane during his convalescence. On discharge from
spital on Oct. 31, 1944, there had been no more pyrexia,
d he had been up all day for three weeks.

SECOND CASE

A female sales clerk, aged 20, who came from a healthy
nily and had had no serious past illnesses, began in May,
44, to have pain on bumping her iliac crests, and shortly
erwards developed a dull central lumbar backache. After
ree weeks she was admitted to hospital, and for the next
ne weeks continued to have pyrexia (103°F each evening).
vestigations did not reveal the cause of her condition, and
August 30 she was admitted to the General Hospital,
irmingham.

ondition on Admission

A nervous uncoöperative girl, very pale and wasted. Iliac
ests and upper ends of both femora and lumbar spine
ry tender on pressure. Abdomen showed generalised
nderness but no palpable tumours. Respiratory, cardio-
scular, and central nervous systems normal.

vestigations and Progress

Blood.—On August 31 a count showed: red cells 2,000,000
r c.mm., Hb 34%, white cells 9400 per c.mm. (myelocytes
5%, unsegmented polymorphs 30%, polymorphs 30%,
sinophils 1%, lymphocytes 25%, monocytes 1·5%). *Blood-*
lture (Sept. 9): sterile.

Radiography of pelvis (Sept. 3): "There is an osteoporosis,
it it is symmetrical, and there is no localised bone
struction."

Urine (August 30): faint trace of albumin; deposit con-
ined a few pus cells; (Sept. 3) no albumin. *Fæces* (Oct. 10
d 19): no pus or blood seen; no non-lactose-fermenting
cilli grown on culture; no tubercle bacilli seen micro-
opically.

The pyrexia continued, not responding to a course of peni-
llin 1,000,000 units. The anæmia was treated by repeated
ood-transfusions. From the time of her admission to the
eneral Hospital until her death on Nov. 10 she was mentally
stable and resented examination. The diagnosis was
ally made by further radiography, which showed a wide-
read osteoporosis of the spine, pelvis, skull, and right femur,
ggesting a generalised neoplastic invasion of bone. There
as no evidence of secondary deposits in the lung. On Nov. 9
biopsy specimen taken from the right iliac bone was found
be infiltrated with secondary deposits of hypernephroma.
ecropsy was refused.

DISCUSSION

In case 1, throughout the patient's stay in hospital,
ere was no evidence of secondary deposits; and, as
is temperature fell to normal after removal of the kidney tumour, it is suggested that the cause of the pyrexia was the necrosis in the centre of the tumour. The significant features of the investigations undertaken were the absence of abnormal urinary findings, the progressive anæmia and loss of weight, and the mental changes. The initial albuminuria was attributed to the fever, as it disappeared after the patient had been confined to bed for two days. The mental changes became prominent and were not controlled by the administration of nicotinic acid in full dosage; they were presumably toxic in origin and again related to the necrosis in the tumour.

The final clue to the diagnosis was the right lumbar pain, followed a week later by a palpable tumour in the loin; but these symptoms did not appear until the patient had been ill for four months.

The early stages of case 2 were not observed, but it is probable that, in spite of the negative radiological findings, her pyrexia was mainly due to secondary neoplastic deposits, as bone tenderness was her first symptom.

SUMMARY

Two cases of pyrexia of uncertain origin, eventually shown to be due to hypernephroma, are described. The pyrexia was attributed to a central necrosis in the tumour in one of them, and to secondary deposits in the other.

In pyrexia of uncertain origin hypernephroma should be considered a possible cause.

We are indebted to Dr. A. P. Thomson for his helpful advice, and to Sir Walter Haward, D.G.M.S., Ministry of Pensions, for permission to publish case 1.

MICRO-ESTIMATION OF NON-PROTEIN NITROGEN IN SERUM, PLASMA, OR BLOOD

F. RAPPAPORT F. EICHHORN
Ph.D. Vienna

From the Beilinson Hospital, Petah-Tiqva, Palestine

WE describe here a method of estimating the non-protein nitrogen in blood, serum, or plasma in 5–10 minutes. The results are equal in exactness to those obtained by the original Kjeldahl method, though no digestion and no distillation are needed.

By our method not only urea and ammonia but also physiological amino-compounds can be determined. Only indole compounds, containing nitrogen in their ring, remain unaffected; but this does not matter, because normal blood contains only traces of these compounds, which even in uræmia do not exceed 0·4–0·5 mg. of nitrogen per 100 c.cm.

The principle of the method is as follows: to blood, serum, or plasma filtrate an alkaline hypobromite-borate solution is added, and the excess of bromine is iodometrically titrated, whereby 1 atom of nitrogen requires 3 atoms of bromine.

REAGENTS

(1) Deproteinisation Fluid[1]:

In a 1000 c.cm. measuring flask 44·8 c.cm. of a 10% sodium-tungstate solution, 2 g. of sodium citrate, and 6·4 g. of sodium sulphate are dissolved in about 800 c.cm. of distilled water, 44·8 c.cm. of *N* sulphuric acid and 2 g. of cadmium sulphate are added, and the flask is filled with distilled water.

(2) Hypobromite Solution:

(*a*) 84·5 g. boric acid and 15 6 g. sodium hydroxide are dissolved in about 500 c.cm. of distilled water, boiled for 30 minutes, and after cooling made up to 1000 c.cm.

(*b*) A saturated solution of sodium fluoride (about 5 %).

(*c*) 27 % sodium hydroxide solution.

250 c.cm. of solution (*a*), 150 c.cm. of solution (*b*), and 50 c.cm. of solution (*c*) are mixed together—i.e., 5 parts of (*a*), 3 parts of (*b*), and 1 part of (*c*). This mixture keeps well.

---

[1] Modified Abrahamson's reagent; see Welcher, F. Chemical Solutions, London, 1942.

The powdered succinyl sulphathiazole was placed in a warm dish, and half the quantity of melted cocoa butter was added. The two ingredients were stirred to form a smooth paste before the rest of the cocoa butter was added. When poured into the moulds and set, the finished product was a little over 2 in. long and $^{5}/_{8}$ in. in diameter.

Since there is no standard metal mould for a suppository of this size, glass tubes were made by removing the ends of test-tubes $^{5}/_{8}$ in. in diameter and flaming the rough edges. The tubes were slightly lubricated inside with almond oil and corked at one end. The mixture was poured into the tubes and, when set, the contents were easily ejected with a glass rod. The suppositories are stored wrapped in 'Cellophane' and keep perfectly well at room temperature.

I wish to thank Sir Philip Manson-Bahr, senior physician to the hospital, for his help in the interpretation of the proctoscopic appearances, in the preparation of this paper, and for permission to publish reports on two of his cases; Dr. H. M. Hanschell, hon. medical superintendent, for permission to report one of his cases, and for his help and encouragement; Mr. Barclay for the preparation of a suitable suppository; and Mr. A. H. Walters, F.I.M.L.T., for his pathological investigations. Siccolam was supplied by The British Drug Houses Ltd.

PYREXIA WITH HYPERNEPHROMA

REPORT OF TWO CASES

C. H. CATLIN
M.D. Birm., M.R.C.P.
LATE SENIOR PHYSICIAN

E. W. BINTCLIFFE
M.S. Lond., F.R.C.S.
LATE SENIOR SURGEON

RONKSWOOD HOSPITAL, WORCESTER

F. G. MARSON
M.B. Birm., M.R.C.P.
LATELY HOUSE-PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM

THE association of pyrexia with hypernephroma is well known, but we have found only one recent reference to long-continued fever as the initial sign. The following two cases presented with pyrexia of uncertain origin.

FIRST CASE

A master baker, aged 36, with 18 months' Army service as a driver in the R.A.S.C.; medical category A1. He came from healthy parents and had had no previous illnesses.

On June 19, 1944, he was transferred to Ronkswood Hospital from a rehabilitation centre after being off duty for seven months with recurrent synovitis of the left knee. He complained of loss of appetite and weight for two months and of vomiting after meals, tiredness, and a dull central lumbar backache for a month. The pain was aggravated by exertion, relieved by rest, and bore no relation to food. The total weight lost had been 2 stone in two months. In answer to direct questioning he admitted to a slight cough with scanty mucoid sputum for many years and denied hæmoptysis, melæna, and hæmatemesis. The bowels were regular, and micturition was normal, except for a slight nocturnal frequency (day 4, night 2), without dysuria or hæmaturia.

Condition on Admission

Pyrexial. Obvious recent loss of weight. Teeth apparently healthy. *Respiratory system:* equal expansion; percussion normal; breath-sounds vesicular, with slightly diminished air-entry at the right base; no adventitious sounds. *Abdomen:* no tenderness or palpable tumour; no enlargement of liver, spleen, or kidneys detected. Rectal examination normal. *Skeletal system:* no residual signs of synovitis of the left knee. Full painless movement in all joints, including spine. No tenderness over lumbar muscles, spine, or pelvis. *Cardiovascular* and *central nervous systems:* no ab detected.

He was running a daily temperature, ranging 99–101°F, and had a corresponding tachycardia.

Investigations and Progress

Urine (June 20): sp. gr. 1020; albumin, a haze; no centrifugalised deposit contained a few red cells and cytes; culture sterile. Further specimens on June 2 24 and July 5 and 14 contained no albumin: d before; culture sterile.

Blood.—On June 20 the count was: red cells 5,1 per c.mm., Hb 100%, colour-index 0·98, white cell per c.mm. (neutrophils 77%, eosinophils 1%, basophils lymphocytes 18%, monocytes 3%). Blood agglu (T.A.B. inoculation given twelve months previously) on were: positive to *Bact. typhosum* "H" 1/25, *Bact. typhosum B* "H" 1/250, *Bact. paratyphosum A* "H" *B. dysenteriæ* Flexner 1/50; negative to *Bact. t* "O,". *Bact. paratyphosum B* "O," *Bact. paratypho B. dysenteriæ* Shiga, *B. dysenteriæ* Sonne, *Br. abortus, melitensis.* On July 12 positive to *Bact. paratyph* "H" 1/250 and *Bact. paratyphosum A* "H" 1/625. *culture* on July 5 and 9 was sterile after forty-eight

Wassermann reaction negative, June 28.

Sputum repeatedly negative for tubercle bacilli. (June 30 and July 5): no pathogenic organisms isol direct culture or with selective media. *Radiography* of showed nothing abnormal.

During the first three weeks in hospital the pyrexia maintained. The patient still complained of a slight and occasional vomiting, and had developed a dull the region of the right scapula and round the right margin. He continued to lose weight and Hb fell to his total and differential white-cell counts re unchanged. Clinical examination during this period entirely negative, and his spine and pelvis were radiograp normal. A full course of 'Sulphamezathine' had produced improvement.

On July 22 a blood-culture grew a scanty growth of *aureus*, which was sensitive to penicillin, and from Au to 5 he was given penicillin 500,000 units by cont intramuscular drip, without effect on the pyrexia. August 12 radiography of teeth and sinuses revealed abscesses of $\overline{54|}$; extraction of the affected teeth did *significantly affect the pyrexia.*

About this time he began to sleep badly, became anx and developed delusions of persecution and of his uncleanliness, being convinced that he was infected venereal disease. On Sept. 1 he complained for the first of a localised pain in the right loin. Physical exami did not reveal any abnormality in this situation, and a fu urine examination showed nothing abnormal. On the 8th still complained of this pain, and on examination a firm about the size of an orange was felt in the loin, moving respiration.

The *urinary tract* was then investigated in detail. Midst urine (Sept. 9): no albumin; deposit contained only a red cells and leucocytes; culture sterile. Intravenous graphy (Sept. 9): normal filling of left kidney, but on side only deformed lower calyces seen. Cystoscopy retrograde pyelography (Sept. 11): bladder and ure orifices normal; catheter passed easily into right ureter retrograde pyelogram showed right renal pelvis and cal. dilated and upper ones grossly deformed. Urea clea test (Sept. 11): blood-urea 24 mg. per 100 c.cm.; mean function 92% of normal. X ray of spine and pelvis (Sept 1 no evidence of secondary deposits.

Hypernephroma of right kidney was diagnosed and o tion decided on. Until the operation patient continued have persistent pyrexia and, during his three months hospital, had lost a further 2 stone in weight. Hæmogl had fallen to 64%, with red cells 3,500,000 per c.mm.

Operation and Recovery

Right nephrectomy (Mr. E. W. Bintcliffe) on Sept. 15. large mass was found adherent to the upper pole of the kid and extending up beneath the dome of the diaphragm. normal lower pole was discernible. There were num large veins round the tumour, which bled considerably du the operation. The ureter and pedicle were isolated w difficulty, and the kidney and tumour removed intact. specimen removed consisted of a tumour occupying the u two-thirds of the kidney. On its surface were num

Case 2.—A man, aged 73, had suffered ten years from a rineal dyskeratosis, with ulceration suggesting malignancy. n May 9, 1945, the lesions had been electrocoagulated, and stological examination had shown a skin-invading glandular ithelioma. Shortly after this operation urinary trouble peared, and per rectum the prostate felt large and hard, th a woody nucleus on one side and a hard region on the her.

Stilbœstrol 10 mg. daily was given from Nov. 24. In ember, 1945, and January, 1946, the urinary function roved, but the indurated area in the prostate tended to ad, and the general condition worsened. Stilbœstrol was efore discontinued, and Y59 20 mg. daily was given from . 4.

n April rectal examination showed an obvious reduction he hardness of the prostate, but the rectal mucosa had eloped anew a glandular epithelioma. The rectum was cted on May 29, when no macroscopic signs of invasion ards the prostate were found. From this date Y59 atment was interrupted, the operation having been very austing. In August the urinary troubles reappeared h more pain than ever, and the patient lost 13 kg. in ight. Stilbœstrol 10 mg. daily was prescribed without effect. t the end of September Y59 therapy was resumed (20 mg. ly). There was a rapid improvement: on Nov. 13 ient was in excellent condition, had regained his initial ight, and had no more urinary trouble. He has resumed occupation.

his patient reacted well to Y59, and stood very well operation for excision of the rectum at the age of 73.

ase 3.—A man, aged 69, with six months' history of poly- a and dysuria, was first examined on March 4, 1946. Per tum the prostate was hard all over, particularly at the edges. ince stilbœstrol 5 mg. daily for 00 weeks produced no provement, Y59 20 mg. daily was substituted. After a nth there was slight functional improvement and the state was less hard.

On July 24 the general condition was fairly good, the local ions remaining stationary.

At the beginning of August the Y59 was discontinued, d on August 23 his condition was worse. The Y59 was erefore prescribed again, in association with radiotherapy a dose of 12,200 r.u.

On Sept. 25 the patient had obviously improved, the ostate was smaller and the urinary trouble less acute. provement still continues.

Case 4.—A man, aged 57, with six months' history of urnal and nocturnal polyuria with dysuria and bad general alth, was first examined in October, 1945. Per rectum e prostate felt as hard as wood throughout.

Stilbœstrol 20 mg. daily was prescribed. In December ere was functional improvement, but œdema of the lower tremities appeared, and a glandular swelling developed in e right iliac fossa. The prostate remained unchanged.

At the end of January, 1946, the stilbœstrol was stopped d Y59 20 mg. daily was substituted. After two months of is treatment the pain and œdema decreased slightly, but e glandular swelling in the right iliac fossa persisted. The ostatic signs did not improve, and the patient's general ndition was becoming worse. Bilateral orchidectomy was rformed, but still without success, and a swollen gland peared at the root of the neck.

The patient died in July, just after a course of radiotherapy d begun. Determinations of the serum phosphatases during e different treatments gave the following results:

Date	*Serum phosphatase (units per 100 c.cm.)*		*Treatment*

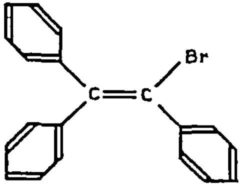
† Normal 3–13 units per 100 c.cm.

DISCUSSION

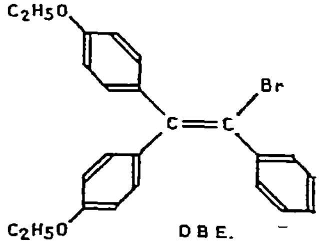
The observations to date suggest that Y59 is sometimes beneficial in cases of prostatic cancer resistant to stilbœstrol. Though Y59 cannot be said to cure the cancer, it does seem to put a partial or even a complete stop to its further growth. Radiography shows that metastases in the bones cease spreading; but as soon as treatment is interrupted the general condition deteriorates again, and, as with stilbœstrol, Y59 must be taken continuously without a break.

During treatment with Y59 we have not noted any digestive trouble or intolerance. Patients sometimes complained of tingling and a feeling of tension in the region of the breast, but did not have any real pain, and objective examination never showed either hypertrophy or adenoma of the breast.

Greene (1946) has reported negative results in one case of prostatic carcinoma with D.B.E., a substance of similar molecular structure and slow destruction but with a greater œstrogenic potency than Y59. Unfavourable results in clinical trials of D.B.E. have also been reported by Haddow (1947). Good results with very large doses (1346 g. in thirteen months) of chlorotriphenylethylene, another substance akin to Y59, have been reported by Watkinson et al. (1944) in one case of prostatic cancer, which was subsequently treated with stilbœstrol.



Y.59



D B E.

Our clinical studies with Y59 lead us to the conclusion that the therapeutic efficacy of this type of substance against prostatic cancer does not depend on its œstrogenicity, and that the beneficial effects of œstrogens are not exclusively due to a "biochemical castration." This leads us to question whether completely non-œstrogenic substances may not also exert a beneficial effect by some kind of direct action on prostatic epithelium, as has already been suggested by Kahle and Maltry (1940), and Kahle et al. (1942) in the case of stilbœstrol. Research along this line is now being pursued.

"... Outside observers are aware of something new and important going on in Great Britain ... yet the mass of the people show very little sign of awakening to the responsibility which rests upon them. It was not until the fuel crisis occurred that the mass of the nation was roused to some sort of bewildered realisation that they were being called upon, in circumstances of great difficulty, in a country impoverished by war and in a world bedevilled by shortages of the most essential food and goods, to conduct a major experiment in social engineering which would call for a quite exceptional degree of understanding and devotion on the part of every man and woman in the country."—From *Planning* (1947, 14, 39) broadsheet issued by P.E.P.

(3) *Bromine Solution:*

(a) 20 g. of potassium bromide is dissolved in about 50 c.cm. of distilled water, 8 g. of pure bromine (2·5 c.cm.) is added, mixed till the bromide dissolves and made up with water to 1000 c.cm.; or

(b) 32 g. of potassium bromide and 2·8 g. of potassium bromate are dissolved in some water in a 1000 c.cm. measuring flask, 100 c.cm. of N sulphuric acid is added, and after waiting for 30 minutes the flask is filled with distilled water.

To 9 parts of the hypobromite solution (2) 1 part of the bromine solution (3) is added directly before use.

(4) *N/200 sodium thiosulphate.*

(5) *Potassium iodide crystals.*

(6) *0·25% starch solution.*

(7) *18% hydrochloric acid.*

Cadmium sulphate is added to the deproteinisation fluid because, in working with blood, hydrogen-sulphide compounds appear in the filtrate which require relatively much bromine (1 H_2S requires 4 Br_2). Cadmium sulphate, however, precipitates all sulphur compounds.

The hypobromite solution contains boric acid to hinder any reduction by glucose by binding the latter as a complex compound. It has been proved that in the presence of boric-acid ions even large amounts of glucose are not affected by hypobromite.

PROCEDURE

Store in short stoppered test-tubes 5·04 c.cm. of deproteinisation fluid (1).* With a capillary pipette measure into the fluid 0·1 c.cm. of serum, plasma, or blood drawn directly from the finger. Wash the pipette by repeatedly sucking in and blowing out the fluid. Centrifuge, or allow to stand for 5 minutes and filter.

In two wide test-tubes or flasks place 4 c.cm. of the clear centrifugate or filtrate and 5 c.cm. of the hypobromite solution (2). Mix and allow to stand for 1–2 minutes. After adding a few granules of potassium iodide and 2–3 c.cm. of the hydrochloric acid (7) to each sample, titrate with *N*/200 thiosulphate till yellow; add a few drops of starch solution (6) and continue the titration until the blue colour disappears.

As blank use 4 c.cm. of deproteinisation fluid (1), adding 5 c.cm. of hypobromite solution (2).

Calculation.—The difference between the number of c.cm. of thiosulphate required for the blank (B) and that required for the estimation (E), multiplied by 0·0467 (= atomic weight of nitrogen divided by 300), gives the nitrogen of the estimation in mg., if *N*/100 thiosulphate is used. Working with 0·0778 c.cm. of testing material ($5{\cdot}14 : 4 = 0{\cdot}1 : x \therefore x = 0{\cdot}0778$) and *N*/200 thiosulphate the difference multiplied by 30 gives the amount of nitrogen in mg. per 100 c.cm.

$$\frac{0{\cdot}0467 \times 100}{2 \times 0{\cdot}0778} = 30.$$

$$(B - E) \times 30 = \text{mg. nitrogen per 100 c.cm.}$$

Accuracy.—Compared with the Kjeldahl method,[2] the rapid method gives almost identical results, as the following example shows.

Non-protein nitrogen in mg. per 100 c.cm.

Kjeldahl ..	19·9	21·3	31·1	31·1	15·5	23·3	44·0	131·0	213·5
Rapid method ..	19·5	21·0	31·5	30·0	15·3	24·0	43·5	135·0	213·0

SUMMARY

A rapid and exact titrimetric method for the estimation of non-protein nitrogen without digestion and distillation is described. Inaccuracies likely to occur in the original more time-consuming Kjeldahl method are here avoided.

TREATMENT OF PROSTATIC CANC

WITH α-BROMO-α.β.β-TRIPHENYLETHYLENE (Y5

M. BERGER NG. PH. BUU-HOI

From the Radium Institute of the University of Par

THOUGH stilbœstrol has been used with great in prostatic carcinoma, some cases are resistant to treatment; moreover intensive dosage with stil has been shown to cause mammary carcinoma in (Lacassagne 1938, Shimkin and Grady 1940), and mary carcinoma has been noted in patients after ment with very large doses (Darget 1946). These led us to look for substances which though less œstr were still potent in prostatic cancer. Since the aim to deal with cases resistant to stilbœstrol, pref was given to compounds with a molecular stru quite distinct from that of stilbœstrol and allied stances.

One compound which attracted our attention *α-bromo-α.β.β-triphenylethylene* (Y59), whose genic activity, toxicity (which is extremely slight), absorption mechanism had already been investi (Lacassagne et al. 1946, Daudel et al. 1946). Th minimal œstrogenic dose, determined on mice by Allen-Doisy test, was about 10 μg. as against 0·1 for stilbœstrol. On the other hand, the enzym destruction of Y59 by living tissues is slower than of stilbœstrol; hence sufficiently large doses of Y produce very protracted œstrus, a fact which may of general therapeutic significance. Further, a st of the metabolism of Y59 marked with radioactiv bromine (Lacassagne et al. 1946. Daudel et al. 19 showed a selective accumulation in the preputial gla whose function has been associated with that of prostate (Gutman and Gutman 1938).

About 20 cases of prostatic cancer have been or being treated with Y59, by mouth in cachets contain 5 mg. The daily dosage was 15–20 mg.—considerab less than the usual dosage of stilbœstrol (up to 30 daily). The following 4 illustrative cases were all resist to stilbœstrol.

ILLUSTRATIVE CASE-RECORDS

Case 1.—*A man, aged 61, first examined on Sept. 1, 19 had a year's history of severe bilateral sciatica with abol of the left ankle-jerk and loss of sensation over the pelvis.*

On examination: His general condition was very bad; per rectum the prostate felt hard throughout, with a har nucleus in the right lobe.

Treatment.—Stilbœstrol 20 mg. daily for a month produced no improvement. The sciatic pain required morphine, and the patient's weight fell to 63 kg.

On Oct. 20 Y59 15 mg. daily was substituted for st œstrol. Eight days later a distinct improvement noted, particularly as regards the pain.

On Jan. 7, 1946, the improvement was remarkable: the patient had gained 9 kg. in two months, he no longer pain at night, and he slept without a sedative. In daytime the perineum was still painful, but the sciatic had disappeared. Per rectum the prostate did not feel hard.

On Feb. 4 the patient was progressing well, his weig had increased to 75 kg., and he felt in very good condit The prostate felt firm but not really hard.

From the beginning of May till June 15 the patient out of town and took his medicine very irregularly. Fr the second week his condition worsened, and pain return When he came back to Paris he had to stay in bed a mo At the end of July he began to take Y59 15 mg. daily more, which brought about a rapid improvement.

The patient is now in good general condition, weig 74 kg., has a good appetite and no urinary trouble, complains only of slight perineal pain.

In this case, after the complete failure of stilbœstr Y59 proved remarkably successful; its good effects continue twenty months later.

Reviews of Books

Sensory Mechanism of the Retina

RAGNAR GRANIT, M.D., director of the Nobel Institute for Neurophysiology, Stockholm. London: Oxford University Press. 1947. Pp. 412. 35*s*.

Dr. Granit believes that his book will be read mainly for its fourth and last section, dealing with the results of five years' intensive work on the colour sensitivity of the vertebrate retina obtained with his micro-electrode technique. He is probably right, for colour vision is in the news nowadays and he has given us many new and sorely needed objective data. His dominator-modulator conception, which separates the perception of brightness from that of hue, modifies the famous Young-Helmholtz theory of colour vision in a fascinating way. No-one who has visited Granit's laboratory and worked with his technique can doubt the validity of his observations on colour sensitivity, but his interpretations seem more questionable. He is almost certainly correct in claiming that he can record the responses of single ganglion cells, but he does not claim that these represent the reactions of single visual receptors. He does believe them, however, to represent groups of receptors acting as units. Owing to the extreme complexity of the nervous structure of the vertebrate retina, and particularly to the probable connexion of both rods and cones to many of the single ganglion cells in the animals he studied, as well as to the lateral connexions between neighbouring bipolar and ganglion cells, it seems probable that the actual pattern of impulses put out by any one ganglion cell is the result of the interactions, through both excitation and inhibition, of many groups of visual receptors. In nearly all the experiments the whole retina was stimulated, though the responses of single ganglion cells were recorded. Granit may possibly assume too readily that these responses represent single retinal "elements" (made up of a group of visual cells with their synapses all acting together as a unit), which he calls dominators or modulators according to the shape of their colour-sensitivity curves.

The interest of this particular section (which is one of the most readable) may cause the real value of the other three to be overlooked. In these, for the first time, most of the known facts about visual purple, the electro-retinogram, and the physiological effects of light and dark adaptation are gathered together and critically appraised. The account of visual purple alone would make the book important to the advanced student or the research-worker in visual physiology. The electro-retinogram, and the way it changes according to the type of retina (i.e., whether dominated by rods or by cones) and the state of adaptation, is unfortunately described in a way which those who are not neurophysiologists may find hard to follow, but the sections on it deserve careful study by all those interested in the physiological basis of vision.

The Road to Maturity

Editor: EDWARD F. GRIFFITH, M.R.C.S. London: Methuen. 1947. Pp. 232. 7*s*. 6*d*.

IN discussing how best to introduce adolescent boys and girls to sex as a natural and universal phenomenon, without surrounding it in clouds of mystery, Dr. Griffith is helped by the headmasters of Rugby, Marlborough, and St. Christopher's, Letchworth, by the headmistress of Cheltenham Ladies' College, and by Mr. T. F. Tucker who writes on elementary and secondary schools. It is a pity that the small minority of children who attend boarding-schools should thus get more attention than the majority who do not, but the balance is restored in a good discussion by Mr. C. W. Gillett (a managing director of Cadburys) of the difficulties facing boys when they enter industry. Mr. Julian Huxley, F.R.S., notes that emotional development can be helped by physical activities, travel, and adventure; and Dr. Noel Harris reviews the main psychological types. The last three chapters of the book, based on Dr. Griffith's lectures to boarding-school boys and girls aged 13, 16, and 18, show sex in perspective as one activity only of a developing organism.

Figures quoted by Mr. Tucker give some hint of the value of sex teaching. In one city 92·3% of children received sex lessons *for ten years*, and of the boys who came *before the juvenile court* for various sexual offences all except one were drawn from the 7·7% who had not attended these lessons in school.

Le fibro-myome utérin

J. DUCUING, professeur de clinique chirurgicale à la Faculté de Médecine de Toulouse; directeur du Centre Anticancéreux. Paris: Masson. 1946. Pp. 537. Fr 7[illegible].

THIS is a well-produced and well-illustrated book by a man who obviously has a strong bias towards radiation therapy. Between 1934 and 1942 he treated 56[illegible] cases of uterine myoma, and he reviews 485 of them. Of these 51 were treated on medical grounds only and are therefore eliminated from discussion, but 74 were treated by operation and 360 by irradiation. The fibroids were small in 154 cases, of medium size in 205, large in 152, and enormous in 36. By "large" Professor Ducuing means the size of a six months' pregnancy and English readers will be surprised and possibly shocked to read of such tumours being treated by radiation; but the author supports this unusual practice with *statistics, and a careful follow-up of the cases he treated.* Although this work does not agree with standard British practice it is worth reading if only to get the other man's point of view. The histological illustrations are good and the operative diagrams clear. His surgical technique does not differ much from the accepted British methods except that he seems to operate entirely with a diathermy knife.

El Diagnostico por la Puncion Esternal (Madrid. Ediciones Morata. 1946. Pp. 317.).—Whether there can be an appreciable demand for so large a book on so small a subject as sternal puncture is doubtful, but Dr. G. Forteza Bover has done useful work for the professional hæmatologist. Published work has been critically considered; and the numerous references to Italian and Spanish papers are of special value to those who see few journals from the Latin countries. The photomicrographs have the usual defect that they require an expert to interpret them, but the coloured pictures leave nothing to be desired. The book calls attention to a useful and novel method of recording the results of marrow biopsy. The author gives a number of graphs which he calls "curves of maturation," and others representing intensity of proliferation. The former are prepared from examination and enumeration of the different stages of each cell-type, while the latter represent the proportions of cells in each stage of mitosis. Like the Price-Jones curve these graphs save the clinician the trouble of remembering normal percentages, since the shape and position of the curves in different stages and types of myeloid activity is characteristic. But the method is laborious and has the defect of the Arneth count that classification of cell-types varies with the observer.

Annual Review of Physiology, 1947.—The editors of vol. IX (Stanford University, California. 1947. Pp. 736. [illegible]) are V. E. Hall, J. M. Crismon, and A. C. Geiso. Among the interesting points discussed this year is the possibility of *preserving skin for grafts by using very low temperatures; this is more successful with autoplastic than heteroplastic* grafts. Peptic ulcer receives a more than usually generous treatment, and attention is drawn to promising results obtained by the administration of extracts of intestinal mucosa. These are presumably due to a substance known to have a depressing action on gastric secretion; its purification, however, is held up by the lack of a simple and inexpensive method of assay. Intravenous catheterisation, familiar as a method of obtaining mixed venous blood from the right auricle, has now been employed for getting blood from the renal vein. The article on the kidney is somewhat provocative on the subject of clearances. The account of cutaneous sensation is a guide to the great advances made during the last few years in our knowledge of the innervation of the skin, and deals also with causalgia and the phantom-limb syndrome. The description of the fractionation on an industrial scale of the plasma proteins is technical but fascinating, including as it does an account of the fibrin preparations and of serum albumin. These are a few of the matters of clinical interest touched on in the reviews, which are in the main physiological and more useful for reference than for reading.

THE LANCET

LONDON: SATURDAY, AUGUST 2, 1947

B.M.A. in Session

xт year the British Medical Association will t to its normal practice of holding its annual ing outside London. Unless the "appointed day" in postponed. the Cambridge gathering will be within a week or two of the inauguration of the nal Health Service, and the representative body doubtless be much occupied in reacting to this ulus This year, on the other hand, the service ied only a small place on the agenda of the sentative meeting; for negotiations with the stry of Health have not yet reached a stage a full report can profitably be given and dis- d. Instead. the three days of debate were based ly on the council's report of the year's work. has been active in many directions, including ry into the care of the aged and infirm, the ons between psychiatry and the law, and the of films in medical education. In his presi- al address Sir Hugh Lett showed particular pride e efforts to strengthen bonds between doctors e Commonwealth and indeed in the world as ole—efforts finding expression in the formation British Commonwealth Medical Council. and mpire Medical Advisory Bureau at B.M.A. e, and in participation in the new World Medical iation which will hold its first annual meeting month in Paris. Together with the more calist activities of the association, which have uring the year to many favourable readjustments muneration and working conditions (including ssful opposition to the principle of the "closed " as applied to doctors), these various and useful vements provided ample topics for discussion.

vertheless the advancing shadow of the new h service was bound to be apparent, and it was esting to try to assess the attitude of representa- towards the events now in progress Early in lebate a note of anxiety was sounded—anxiety se negotiations are going steadily on, leading now not where, and the months are slipping ithout any information which would allow the sion to discuss what is happening. This anxiety nly partially dispelled by Dr. Dain's assurances he and his colleagues are still having profitable in Whitehall, that they have made no con- ns, and that they are still hopefully insistent e need for an amending Act. Assurances were that, when the present talks have been com- , a statement on all the issues raised with the ry's officials will be published, together (it is with the Minister's own reactions and views: ublished this document will form a basis led informed discussion in the divisions he convening of a special representative Even after hearing this explanation, how- meeting was not wholly satisfied · it agreed siderable majority that the Negotiating Com- hould be allowed to go on with their discussions being obliged to make early or frequent reports. but it wanted to be sure that the association would be ready with its own plans for ensuring that such problems as that of the proper distribution of doctors, and of the establishment of health centres, are solved in ways acceptable to the profession. In discussions on the appointments made by the Minister to statutory bodies such as the regional hospital boards, dissatisfaction was expressed that so few B.M.A. nominees had been appointed to boards. Those local health authorities which have so far resisted the Minister's strong recommendations that that should coöpt suitable medical members to their health committees were criticised, and action was demanded to see that there is proper medical representation on statutory bodies at all levels. In so far as regulations and orders already published under the Act are concerned, there was no criticism of the superannuation arrangements, and the recently issued memorandum no. 118 incited displeasure only because of its suggestion that midwifery provided under the Act shall be limited to those doctors whose names are on an approved list of general-practitioner obstetricians.[1] Although this limitation was cogently defended by Dr. Dain himself—and he was not without supporters—the meeting would not have it, and by a vote of 106 to 96 insisted that all registered practitioners shall be entitled to undertake domiciliary obstetrics under the Act.

Generally the impression given by this annual meeting was that the representatives were in a thoughtful and cautious mood, still anxious to resist any part of the new scheme which they thought infringed their rights or privileges—e.g., abolition of the sale of practices, or the restrictions upon the practice of midwifery—but not seeking to condemn it in any wholesale manner, nor to declare any immediate policy of complete non-coöperation. Indeed, where there were opportunities for constructive work on the statutory bodies being set up to administer the Act they were asking for greater chances to help than they have been accorded. Much of last year's controversy, particularly where it concerned hospital policy and the future of the consultant service, seems to have died, and from Dr. Dain's report it seems not impossible that sufficient accommodation may also be secured on the general-practice side to allow an acceptable service to take shape. The special representative meeting to be held later will show whether these hopes are too sanguine; but the atmosphere of this recent meeting suggests that the birth of the new service will take place at its appointed term without further delay in the second stage.

Poliomyelitis Precautions

A Ministry of Health memorandum on acute poliomyelitis which we published last week is prompted by the rapidly rising weekly notification figure, which has already reached the highest level ever recorded in this country. This year the seasonal rise in incidence began nearly a month earlier than usual, and if the disease follows the course to be expected, with a peak incidence about the middle of September, quite an exceptional prevalence is likely before the end of the year. Though the advice now offered by the Ministry differs little from that

ARRESTING

The Male Climacteric

BY PERORAL HORMONE THERAPY

The mental fatigue and diminished bodily energy which characterise the male climacteric respond readily to male hormone therapy in the form of ORAVIRON (British Schering brand of methyl testosterone in tablet form). Depression and nervous instability are eliminated, and the general condition, both mental and physical, shows a steady improvement.

'ORAVIRON' is presented in tablet form in the following sizes:

TUBES *of 20 × 5 mg tablets* TUBES *of 20 × 10 mg tablets*
BOTTLES *of 100 × 5 mg tablets*
BOTTLES *of 100 × 10 mg tablets*

ORAVIRON

msiderably higher concentrations can be main- ined. Oily suspensions, giving a slower " release " penicillin, have been used to assist in building up aximal concentrations, and the various mechanisms y which renal excretion of penicillin is hindered ay be employed to the same end. Since the serous embranes, even when inflamed, are a partial barrier the diffusion of penicillin, the problems of preserving high concentration in the cerebrospinal fluid or the leural cavity are less difficult. Toxic reactions penicillin have become rarer as the product has een further refined; with the crystalline substance ow marketed they are said to be absent. Allergic actions appear to be related to idiosyncrasy rather ian to dosage. In short there seems to be no reason hy concentrations high enough to inhibit the growth several organisms earlier regarded as insensitive ould not be used in therapeutics. A word of rning, however, is necessary: it is recognised that, th in vitro and in vivo, organisms of the same ecies vary greatly in their response to antibiotics. hen dealing with organisms that are sensitive only the higher concentrations, the coöperation of the cteriologist is almost essential.

Published experiences support this thesis. Others ve failed to repeat MCSWEENEY's[10] success in treatg enteric with 2 mega units per diem in combination th sulphathiazole; but the weight of evidence is at some cases at any rate are benefited by this eatment. Similarly some though not all infections ith proteus apparently yield to a sufficient dosage penicillin.[9 11] Early work suggested that *Hæmoilus influenzæ* is resistant to penicillin, and treatment meningitis due to this organism was not attempted. was not until 1945 that it was shown[12] that, though is resistant in the rough phase, recently isolated rains in the smooth phase are sensitive to a varying egree. Clinical trials reported in this issue indicate iat acceptance of a probably fatal outcome of . *influenzæ* infections is no longer permissible. In iese trials the concentration of penicillin in the rebrospinal fluid is not recorded; but there is reason suppose that, with the dosage adopted, a concenation at least of 5 units per ml. is attainable over ng periods. The use of crystalline penicillin seems obviate the danger of the damage to the nervous ssue that was seen with less pure products. The gimen suggested by GOTTLIEB and FORSYTH may e taken as a guide, to be amended as proves necessary. the organism is found to be unduly resistant nd ALLOTT noted that the strains varied widely in nsitivity), or if clinical improvement is slow, there no reason why the dosage, either intramuscular or ntrathecal, should not be increased. No harm can ome from the concomitant use of drugs of the ulpha series, or of immune serum. Probably a urified streptomycin would be even more effective this condition; but the serious and unexplained quelæ to its use in meningitis should make for esitation before it is preferred to penicillin.

That four out of five cases of meningitis due to *I. influenzæ* were successfully treated with penicillin ives rare support to the Hunterian method at the xpense of Authority, and may point the way to profitable trials in patients infected with other organisms found resistant to the lower concentrations previously employed. To obtain a local concentration higher than 2 units per ml. is no longer difficult, costly, or dangerous: far more data are required on the relative sensitivity of organisms, especially on primary isolation from the body, but in the majority of bacterial infections the length of the odds against success no longer justifies a charge of " wasting " the penicillin used in their treatment. Plague, undulant fever, perhaps whooping-cough, are, for example, reasonable subjects for continued experiment. It is a safe working rule in most fields of therapy that benefit from any particular line of treatment will be seen, albeit not dramatically, soon after the treatment starts. Using this guide the dosage of penicillin is limited only by the physical difficulties of administration.

THE DENTAL HYGIENIST

FOR the second year in succession the number of names on the Dentists Register has fallen—reaching 15,266 last May—and 1946 produced fewer recruits to the practising profession than any year since the Dental Board was established. Though this decline is attributable to the small entry to the schools during the war, and the board foresees a change in the right direction at the beginning of the next decade, improvement is unlikely to be on the scale considered desirable by the Teviot Committee, and may indeed fail to check the fall in total numbers.[1] In these circumstances more and more will be heard about the use of ancillary workers to help in tackling the arrears of dental work which are so painfully conspicuous today. In the statement reported on p. 186, the Minister of Health denies any intention to dilute the profession in any way, but says that the Government, following the suggestion of the Teviot Committee, want a proper test of the possible advantages of using dental hygienists.

It is important not to confuse two different types of auxiliaries—dental assistants as found in New Zealand and dental hygienists as found in the United States. The New Zealand dental assistants are permitted, after an abbreviated course of two years' training by officers of the school dental service, to practise dentistry in the full sense of the word, the only condition being that they limit their activities to school-children and nominally work under supervision. This is pure dilution and clearly unacceptable in this country. Unhappily, the fear of such an expedient seems to be responsible for opposition in the profession to the other type of auxiliary—the dental hygienist.

Dental hygienists came into being in America largely as the result of the work of Fones.[2] Their function is to scale and clean the teeth: they take no part in the treatment of pathological conditions, and their efforts are directed solely towards prevention. During the war the Royal Air Force, largely as the result of the far-sighted policy of its dental consultant, Mr. Kelsey Fry, trained dental hygienists and made good use of them in maintaining the oral health of air-crews.

Recently an experimental clinic for the treatment of school-children has, with the collaboration of the local authority, been established in the Turner Dental School of Manchester University. The clinic will be responsible for the treatment of some 1200 children attending near-by schools. An attempt will be made to translate research

previously given,[1] more attention is paid to the frequent occurrence of a relatively slight prodromal illness which often appears a week or so before the main attack. At this stage the patient is probably as infectious as at any time later,[2] and the importance of isolating any child developing a febrile illness at this time of year—and continuing isolation until poliomyelitis can be excluded—is rightly emphasised. As for treatment, extensive trials in the United States and elsewhere have tended to confirm the view that convalescent serum is ineffective. Prophylaxis by nasal sprays and gargles, which seemed so promising ten years ago, has also been abandoned. Good nursing in the acute stage, and competent orthopædic care, remain the essentials of management in this distressing disease.

The Ministry now apparently accepts three weeks from onset as a long enough period for the isolation of cases. This is a change from the period of six weeks recommended in 1936; but there is remarkably little evidence that poliomyelitis tends to spread in hospitals, and the shorter period conforms with current American practice. Three weeks, from the isolation of the case, is likewise advised as the period during which home contacts should be excluded from school. The closure of day schools when cases are recognised is not regarded as justifiable, since most children have as much contact with other children when their school is closed as when it is open; and the watch for early symptoms is often closer at school than at home. Now that summer holidays are here this administrative problem has solved itself for the time being, but it may need reconsideration when the time comes for the schools to reopen in September. As a guide for boarding-schools the Ministry's memorandum refers to the Code of Rules prepared by the Medical Officers of Schools Association, which was revised and republished last year.[3] For day nurseries and nursery schools, which present a new and special problem, it is thought that prompt closure for three weeks may be the wisest course when a case is recognised among the children attending. As regards quarantine for adult contacts in affected households, as recently advocated in Ireland,[4] it is true that the virus of poliomyelitis has been isolated from the fæces of healthy adults and that the transmission of the disease by such carriers has been invoked to explain certain features of some carefully studied outbreaks, such as the one in Mauritius in 1945.[2] But the administrative difficulties involved in an effective quarantine of adult contacts seem almost insuperable. There is no practicable means of enforcing restrictions of this sort, and to attempt to apply them in urban industrial areas would cause awkward complications, including demands for compensation for loss of earnings. Further, the identification of healthy carriers by laboratory tests is not at present possible on what might be termed the "typhoid fever" scale.

On the advice to be given about crowded assemblies and gatherings of young children in their districts, medical officers are left to decide for themselves. Where many cases have occurred they will usually feel justified in warning the public that because spread is believed to be mainly by human contact all unnecessary aggregation—particularly of children—should be avoided. Cinema shows for children are obviously a potential risk; and also, possibly, swimming-baths. It has never been established that swimming-bath water polluted by virus-bearing excretions has spread poliomyelitis, but the plea for closure of baths, repeated in our correspondence columns this week, is supported by SABIN.[5] Sensible precautions are the avoidance of excessive physical exertion in children at competitive sports and games, and the postponement of non-urgent operations on the throat and nose. The possibility of the disease being spread by flies must clearly be borne in mind, especially as the virus of poliomyelitis has on occasion been recovered from flies which have had access to the excreta of infected persons. Though there has been suggestive evidence,[6] no clear instance of transmission by fly-contaminated food has ever been reported, and there is no obvious correlation in this country between the prevalence of flies and outbreaks of the disease. But the protection of food from flies is rightly described by SABIN as a "reasonable and warranted" part of our precautions.

Not Necessarily Invulnerable

MOST of us can recall the awe with which we handled the first samples of penicillin which came our way; it promised so much and there was so little to be had. We did not lavish it on all and sundry—as was customary with sulphanilamide ten years before—but rather were guided by Authority in the form of the published tables showing which organisms were sensitive to its action and which were not. Those of the first group responded beyond expectation to the recommended dosage of 12,500 units three-hourly; for infections by the second group we fell back on the rest of the pharmacopœia. Sometimes we received hints that we missed: the mixed infections of wounds caused by penicillin-sensitive staphylococci and insensitive "coliforms" responded remarkably well to treatment directed at the former only.

Further experience and improved technique soon made it evident that a third group of bacteria should be recognised—organisms which are "partially sensitive," or sensitive to penicillin in higher concentrations than those needed to inhibit the standard staphylococcus (whose position as the yardstick of susceptibility is, after all, the result of chance rather than of deep understanding). BIGGER[7] showed that a concentration of 2 units per ml. is inhibitory (though not bactericidal) to *Salmonella typhi*, and WINSTON EVANS[8] that the majority of typhoid strains are susceptible to a concentration of 10 units per ml. Figures of the same order were obtained for proteus,[9] for *Pasteurella pestis*, and for some strains of *Vibrio choleræ*. These findings were the result of observation in vitro, and their clinical significance seems to depend mainly on how large a concentration of penicillin can be built up in the tissues. By the use of 2 mega units or more daily a concentration of 2 units per ml. can be obtained in the serum; and with continuous injection

sires alcohol; (2) that an addict to alcohol is often neurotic; (3) that neurosis creates a demand for rtain metabolites which can be supplied by alcohol; d (4) that neurosis is not only a mental change but so a physical change. He warned his hearers against ducing that neurosis should be treated with alcohol; e lesson he himself drew was that the addict to cohol must be treated for the underlying neurosis.

CORPORATION FOR CARE OF THE OLD

THE Rowntree committee's report[1] convinced the uffield Foundation that some central agency equipped ith large funds is needed to look after the welfare of d people. They have therefore decided to sponsor a ational Corporation for the Care of Old People. Lord uffield was present at a meeting held, by invitation of r Bracewell Smith, the Lord Mayor, at the Mansion ouse, London, on July 28, when Sir William Goodnough announced that the Foundation have undertaken o provide £500,000 in the early years, and that the ord Mayor's Air Raid Distress Fund is adding a substantial sum for grants to be made towards help for old eople who have suffered distress from air-raids. It is oped that the corporation, which will be principally oncerned to find funds, will also attract large and small ums from other sources. The governing body has een appointed equally by the Foundation and by the Air Raid Distress Fund, and consists of Sir George Wilkinson s chairman, the Lord Mayor, Sir Frederick Wells, the Hon. Geoffrey Gibbs, Lady Somerleyton, and Mr. L. Farrer-Brown. An expert advisory council will suggest policy, recommend activities, and examine applications to the corporation.

The aim is "to encourage and support the efforts of local and national voluntary bodies working for the welfare of the aged, and particularly to assist them to provide in a kindly and efficient manner for the accommodation and care of old people, especially those who are lonely, infirm or invalid." The corporation will therefore be empowered to make grants and loans towards schemes for these purposes, and to accept gifts and hold property on trust. They will go further, maintaining an expert advisory and consultant service on technical points, and offering grants and loans to areas found to be backward in the care of the old. They will not be able to assist individuals seeking accommodation or financial help. Those bodies or authorities receiving grants will be required to maintain approved standards in homes or other schemes. The corporation will also encourage and undertake research and experiment, and publish the results. Integrated work between local authorities and voluntary bodies will be fostered, the corporation acting as the welcome complement and ally of the National Old People's Welfare Committee, which stimulates and organises local interest.

The value of such a corporation at this time is bound to be great, and the trustees of the Nuffield Foundation are to be congratulated on such an opportune and constructive project. In their second annual report[2] they foreshadow some of the developments they consider necessary. The most pressing problem, they suggest, is the need for more accommodation of various kinds; and they are ready to support well-conceived schemes for the adaptation of houses and for new buildings. So many different types of quarters are in use up and down the country that there is no need to experiment with different varieties: the important thing is to provide enough of each type, and see that they are integrated with the existing services for the old. Each area needs a comprehensive range of accommodation, so that old people can be transferred from one type to another, as their necessities demand, without trouble and distress, whether the need for transfer springs from failing or improving health. Their place must be among the younger people in the community, in order both to keep the old people lively and the young aware of their responsibilities towards the welfare of the old. The quarters provided should range from small houses, bungalows, and flats to residential clubs, communal homes, homes for the infirm and long-term sick, beds for the treatment of acute illness, convalescent homes, places where old people normally living with relatives can stay for short periods, and clubs providing meals and recreation rooms. The Foundation are concerned principally with schemes of a pioneer type, and have already received and examined many projects for immediate grants. A few grants, indeed, have been made already, including £2000 a year for two years to the National Old People's Welfare Committee, and £5000 to the Hill Homes, Highgate,[3] towards the purchase and equipment of a fifth home. The Hampstead Old People's Housing Trust, which hopes to provide for lonely and infirm old people who need care and attention, has been granted £3500 towards acquiring and adapting a house; and the Foundation have promised a grant of £15,000 towards a scheme for the housing and care of able-bodied and infirm old people in Colchester, provided the town raises the balance (£22,000) in a year. A grant of £10,000 has been offered to the Elderly Nurses' National Home, Bournemouth, to improve and enlarge the present sick-bay and increase the number of single rooms; and a further grant of £10,000 has been offered to the Christchurch (Hants) Old People's Welfare and Housing Society, to adapt two houses, one as a second residential home and the other as a rest home.

TREATMENT OF HYDRAMNIOS

HYDRAMNIOS is a serious obstetrical complication which, according to DeLee, arises about once in 200 labours. It is often associated with developmental abnormalities in the fœtus, such as monsters, spina bifida, and anencephaly. Treatment in such cases is surgical induction of labour, with no thought for the fœtus. A good radiogram will usually reveal fœtal abnormality, and one should be taken in every case of hydramnios before the treatment is decided on.

In the rare cases where hydramnios is associated with a normal fœtus the correct treatment is also as a rule fairly clear. The condition usually occurs between the sixth and eighth month, when induction of labour will produce a premature fœtus with small chances of viability. The accepted principle in the past has been to treat such cases conservatively as long as possible so as to give the fœtus the best chance of survival; interference has been resorted to only when the maternal condition demanded it. Abrams and Abrams[4] suggest that ammonium chloride is useful in reducing hydramnios, and in a preliminary report on two cases they show good results. They gave gr. 90 of enteric-coated tablets daily for seven days in one case, and gr. 75 daily for seven days in the second case; this produced diuresis, loss of weight, and reduction in uterine tension. In both cases live normal babies were born and both patients had normal deliveries. Abrams and Abrams claim that the drug is harmless to the mother, but it would be advisable to watch the urine carefully for signs of renal damage, such as the passage of albumin and casts, during the exhibition of the drug.

findings into clinical practice, and to assess their value, both from the point of view of results and also from the cost in professional time. Obviously, with the present shortage of dentists, the value of any method of prevention or treatment will depend largely for its effectiveness upon the number of cases that can be dealt with by one man. Accordingly the Minister of Health, under the Dental Act, has granted permission for use to be made at the Manchester school of two or three dental hygienists, who have been trained in the Royal Air Force and who have passed an approved examination, and who on demobilisation wish to continue with the work. These women will instruct the children in the proper use of the tooth-brush and will periodically clean the children's teeth themselves. They will work under supervision, and will not fill teeth or attempt to treat any pathological condition; their job is entirely one of prevention. Apart from other considerations, the fact that the dental hygienist does something for the child will greatly enhance the value of propaganda to develop "tooth consciousness." She will also assist the dental surgeon by cleaning the mouth of patients and preparing the field in which he is going to operate.

ARTIFICIAL LIMBS

Time marches on, and so, fortunately, do wooden legs. The modern descendant of the old peg-leg is made in 'Duralumin,' but this material will doubtless give place in turn to something new—lighter but equally hardy. Already magnesium and its alloys have been considered for certain parts of artificial limbs, but tests carried out by the research department of Queen Mary's Hospital, Roehampton,[1] in conjunction with the metallurgical department of the National Physical Laboratory, have shown that these alloys are not strong enough and are too readily attacked by water and by electrolytic reactions. The standing advisory committee of the Ministry of Pensions, in their first annual report, mention other new substances tried for various accessories to the limbs—plastics as a substitute for leather, and nylon for surgical corsets, nowadays worn by women to suspend the artificial limb instead of an uncomfortable leather belt. Though these two materials have objections, it seems likely that other and better ones will come along soon. Since the appointment of the committee, 108 suggestions for improving artificial limbs and appliances have been received from the British Limbless Ex-Servicemen's Association, the British Legion, St. Dunstan's, doctors and limb-fitting surgeons, non-research members of the staff of the Ministry of Pensions, disabled persons, private firms, and members of the general public. Of these, 39 were accepted for research and experiment, but 15 were given up after further study; though many of the remaining 69 were ingenious, they would either have proved too heavy, or were unsuitable for incorporation in an artificial limb, or were too difficult to manufacture, or offered too much chance of breakdown, or were similar to designs already being used by the Ministry.

The research centre, under Dr. A. W. J. Craft, is experimenting with a special type of socket, for above-knee limbs, shaped to allow for normal contraction and expansion of the thigh muscles, and patients trying these are giving favourable reports. Suction sockets, popular on the Continent though discarded here after experiment in the 1914–18 war, are being given another trial, and foreign knee-mechanisms are also being studied. A redesigned artificial arm, with more flexion and more intermediate locking-positions at the elbow, and a naturally shaped wrist, is now being tried by a patient; while another pattern of arm is being made which can be set at any degree of flexion. A complicated mechanical hand submitted by an inventor proved dis being too heavy, with too many appendages and thumb which was difficult to control.

The appliances provided by the Ministry for an artificial limb have been criticised for being specific and too numerous. Patients now receive "universal appliance" which serves the turn of including the spade-grip, the carpenter's appliance, others. Several appliances have been redesigned suit the patient's work. Thus letters can be taken any direction by the sorter from the "postman's" and a small additional fitting enables him to tie mail-bag without changing the appliance. A lock on the "writing hand" enables the wearer to suitcases, handbags, and parcels without risk of them slip. Several new appliances have been for the man who has lost both arms, all giving him independence not only at work but in his toilet. accessory gadgets to help these disabled men rubber suction cups which can be attached to objects to stabilise them—fixing the egg-cup to the example, or the nail-brush or bath-brush to the the bath.

Statistics are being collected on the wearing of limbs and parts of limbs, as well as on the of various amputation sites. Foreign methods of making and limb-fitting and foreign operations, the cineplastic and Krukenberg operations, are also studied, and a German type of elbow-crutch with scopic assembly is being manufactured for trial Roehampton patients, who always prove interested coöperative.

THE LONGING FOR ALCOHOL

In his Kelynack lecture, delivered on July 15 to Society for the Study of Addiction, Prof. F. L. Golla, director of the Burden Institute, Bristol, dealt with the origin of a desire for alcohol. Metabolism, he said, regulated through the mechanism of taste. For example, herbivora require salt and therefore want and like it whereas carnivora do not. The metabolism of salt regulated by the suprarenal cortex: sometimes pe with a suprarenal cortical lesion become gluttonous salt; and in rats experimental destruction of the cortex leads to a similar lust for salt, with increased sensitiveness of the taste-buds to its presence in solution. Similarly, a rat with a pancreatic lesion causing diabetes, if given a choice of different food, will be greedy for fat and take a little more protein than usual, but will not touch carbohydrate. Both schizophrenic patients and animals injected with insulin and offered simultaneously (1) water, (2) 5% sucrose, and (3) 30% sucrose choose that drink which is physiologically requisite according to the amount of sugar in their blood. These experiments of Richter and others suggest that some change must be produced in the mechanism of taste, and it would be reasonable to suppose that the desire alcohol may arise in somewhat the same manner.

Professor Golla cited the work of Masserman, has produced anxiety neurosis in cats by inducing first a conditioned reflex and subsequently substituting irregularly a wrong sequence (electric shock instead food). It was found that such a neurosis could be caused to disappear by giving the cat an intraperitoneal injection of alcohol. Similarly, if the alcohol was injected before the attempts to produce a neurosis, the neurosis did develop. Again, cats with the neurosis, if offered choice of milk or of milk and alcohol, drank the latter with avidity and thus lost their neurosis. On disappearance of the neurosis the cat lost its addiction to alcohol (which normally is most distasteful to cat Then it was possible to precipitate the neurosis a by the usual method. These observations indica Professor Golla thought, (1) that a neurotic needs

NTERNATIONAL CONGRESS OF PEDIATRICS

FROM A CORRESPONDENT

WITH well over 2000 registrations, the 5th International Congress of Pediatrics ran a successful and rowded course during four particularly humid days n New York in mid-July. Pædiatricians from over 0 nations heard Dr. HENRY F. HELMHOLZ, of the Mayo linic, president of the congress, deliver his formal pening address on a platform backed by a huge fan of ll their national flags. The colourful effect was later nhanced when Dr. EMMETT HOLT, jun., the energetic ecretary and organiser of the congress, accepted from r. TSU FEI SU two hand-embroidered banners from the hinese Pediatric Society and the Chinese Medical ssociation. Dr. THOMAS PARRAN, surgeon-general of he United States Public Health Service, welcomed the isitors with a message from President TRUMAN which ncluded the statement: "To promote the health of hildren the world over is a part of our task of building ermanent world peace." Other speakers emphasised he point that child care is of the greatest possible mportance, a fact clearly recognised by the success of his, the largest international medical congress since the war.

THE DISCUSSIONS

The first plenary session was concerned with *Nutrition*. Prof. R. A. MCCANCE (Cambridge) gave an account of his observations in Germany on the weight and height of children under the observation of the special Medical Research Council unit. Dr. J. H. P. JONXIS (Rotterdam) spoke on his investigations of blood chemistry in relation to food deficiencies in children. Dr. J. GILLMAN Johannesburg), observing that in South Africa there are 17 pædiatricians for 4 million children, described his observations on malnutrition. Other speakers included Prof. P. PLUM (Copenhagen), who commented on the increase in cœliac disease during the war; Dr. G. LOGARAS (Athens), who saw the problem in Greece as essentially economic; and Dr. DAG RIIS (Oslo) who mentioned that, despite the poor nutrition, the amount of dental decay had decreased in school-children in Oslo. Concluding remarks were made by Dr. M. S. MASLOV (Leningrad) and Dr. F. F. TISDALL (Toronto).

The second scientific session was divided into three periods. At the first *Diseases caused by Filtrable Viruses* were discussed. Dr. A. B. SABIN (Cincinnati) gave a masterly opening paper on neurotropic viruses, classifying them into those with a basic reservoir in human beings and those with a basic reservoir which is extra-human. He was followed by Dr. L. ALM (Gothenburg) and Prof. H. K. FABER (San Francisco). Prof. T. FRANCIS Ann Arbor) spoke on respiratory viruses, Dr. J. M. ADAMS (Minneapolis) on virus pneumonia in infancy, and Prof. C. A. JANEWAY (Boston) on the modern use of globulins in the control of outbreaks of measles. The second discussion, on the *Chemotherapy of Infectious Diseases* was opened by Prof. C. S. KEEFER (Boston). Subsequent speakers were Prof. G. FRONTALI (Rome); Prof. R. DEGKWITZ (Hamburg), who gave a fascinating account of the use of colloidal particles of azo dyes in the treatment of tuberculosis in animals; Dr. A. BOSÁNYI (Budapest); Dr. M. S. PERDIGUERO (Saragossa); and Prof. W. S. GAISFORD (Manchester), who emphasised the dangers of intraspinal therapy in meningitis. The third subject considered was *Neonatal Mortality*. The opener was Prof. A. A. MONCRIEFF (London), who emphasised the social factors and the need for early care of premature infants. Later speakers included Prof. C. GYLLENSWARD Upsala), Dr. A. REUSS (Vienna), and Dr. A. F. TUR Lenin

The morning of the last day was devoted to a plenary session on *Tuberculosis*. Prof. A. WALLGREN (Stockholm) opened with an account of the rationale, methods of use, and efficacy of B.C.G. in the prophylaxis of tuberculosis. His studies had indicated that the "artificial immunity" produced by the use of this vaccine could last as long as ten years. Prof. K. JONSCHER (Poznan) spoke of the excessive morbidity from this disease in Poland as a result of the war, and he recommended the inoculation of newborn infants by the oral route. Subsequent speakers included Dr. A. CHATTÁS (Cordoba) who spoke of the intracutaneous injection with B.C.G. of newborn infants, now achieved for about half of such infants in his city; Prof. R. DEBRÉ (Paris) who described extrapulmonary primary lesions; Dr. J. HUTCHISON (Glasgow) who discussed bronchial occlusion in primary tuberculous infection and the place of bronchoscopy in treatment; and Prof. G. WEBER (Munich) speaking of the influence of the genotype on the predisposition to tuberculosis.

The afternoon meeting was divided into three sessions. At the first Prof. G. DE TONI (Genoa) opened a discussion on *Incompatibility of Blood* and set out six fundamental questions still unanswered by modern work on the rhesus factor. Dr. B. BROMAN (Stockholm) touched on the possibility of damage to the fœtus by incompatibility due to other mechanisms than the rhesus immunisation of the mother. Some observations on the same aspect were made by Dr. I. HALBRECHT (Tel-Aviv). It was fitting that the concluding speakers in this session should have been representatives of two schools in friendly rivalry—Dr. L. K. DIAMOND (Boston) and Sir LEONARD PARSONS (Birmingham). The second session was concerned with *Alimentary Toxicosis*, the discussion being introduced by Prof. E. KERPEL-FRONIUS (Pécs) who reviewed modern work on water and mineral exchange in diarrhœa and concluded that the primary damage is a failure of circulation due to reduction of plasma volume caused by a loss of extracellular electrolytes and capillary injury. Among other speakers were Prof. L. F. MEYER (Tel-Aviv), Prof. G. FANCONI, and Prof. E. GORTER (Leiden) who though completely crippled by arthritis had made the journey by air from Holland.

The third session, on *Congenital Heart Disease*, was opened by Dr. A. CASTELLANOS (Havana), who in reviewing the subject laid special stress on the value of angiocardiography in arriving at an exact diagnosis and in selecting cases for operation. Dr. E. MANNHEIMER (Stockholm) gave a brief description of the value of fluoroscopy, phonocardiography, and the hypoxia tolerance test. Dr. A. COURNAND (New York) described the use of the radio-opaque catheter introduced into the heart through the venous system. Concluding speakers were Dr. D. KEITH (Toronto) and Prof. M. LAMY (Paris).

The scientific exhibits were of a high standard, numbering over 150 and illustrating some of the recent work in pædiatrics, much of great importance in general medicine. Nearly 40 films, including one from England on *Scabies*, were shown at intervals throughout the meeting.

THE TRANSACTIONS

The programme, giving summaries of papers and descriptions of the exhibits and running to nearly 200 pages, had been splendidly prepared by the *Quarterly Review of Pediatrics* and will be reproduced, with missing abstracts inserted, in the August, 1947, issue of this periodical. Copies may be purchased from the Washington Institute of Medicine, 1720 M Street, N.W., Washington 6, D.C. The official transactions of the congress will be published in *Acta Pædiatrica*, and may be obtained by writing to Almqvist and Wiksells Boktryckeri Aktiebolag, Upsala, Sweden. The next congress will be held in Switzerland in 1950 under the presidency of Prof. G. FANCONI (Zürich).

ŒSTROGENS IN PROSTATIC CANCER

THERE is no doubt that many patients with prostatic cancer, especially if metastases are present in bone, can be greatly relieved for a while by the administration of œstrogens. As a rule stilbœstrol has been used for this purpose because it is cheap and is effective by mouth; moreover extensive trials by clinicians in many countries have not revealed any disadvantages to outweigh its benefits.

In this issue Berger and Buu-Hoi, who are working with Professor Lacassagne in Paris, describe 4 cases of prostatic cancer which stilbœstrol had failed to ameliorate but in which considerable benefit was obtained from a different synthetic œstrogen, α-bromo-α.β.β-triphenylethylene, or Y59 for short. Success followed the use of this drug, though it was given by mouth in amounts not larger than those of stilbœstrol, and in spite of the fact that its minimal œstrogenic dose for mice, as judged by the commonly accepted standards, is about a hundred times greater than that of stilbœstrol. Did Y59 owe its superiority over stilbœstrol in the cases quoted to any peculiar quality? As Berger and Buu-Hoi point out, the œstrogenic capacity of Y59, though slight when calculated by the usual methods of assay, is yet remarkably protracted; and to this durability of action the superiority of Y59 over stilbœstrol in these cases may perhaps be attributed. At any rate the clue seems worth following, in the hope that it may lead to a further advance in the relief of prostatic cancer with œstrogens.

FACTS ABOUT MIDWIVES

ON paper, midwives are plentiful; but in actual fact we have nothing like enough practising midwives to meet our needs. The working party set up by the Minister of Health and the Secretary of State for Scotland[1] has been asked to inquire into the recruitment and training of midwives and any other matters which have a bearing on the present shortage. The problem is clearly quite different from that facing the working party on nursing, for among midwives there are plenty of recruits, most of whom complete the course for part I of the examination, and many for part II. At the end of March there were 74,219 women on the roll of qualified midwives, but only about 16,400 were practising midwifery, some 10,000 of these being in hospitals and 5500 in organised domiciliary services. The working party is anxious to find out exactly what proportion of those who notify their intention to practise actually do so, for at present we are pouring a stream of qualified midwives into a basin with many holes in it.

Several well-known causes of loss at once spring to mind: the demand of many local authorities for a midwifery qualification in those appointed to do health visiting or other social work seems likely to account for a large proportion, while others are lost because hospitals use them as sisters in surgical wards and elsewhere. We have no figures, however, to show what factors are chiefly responsible for the loss, or to what degree, and such figures the working party is determined to procure. To this end it is sending out a questionary to the midwives—more than 17,000 in England and Wales and 1200 in Scotland—who notified their intention to practise midwifery in 1944.

They ask 18 questions, most of which are divided into several parts. The first five ask for personal data, merely so that it will be possible to check the age-groups and qualifications of those who fail to answer. Other questions ask whether the midwife notified her intention to practise in 1945, 1946, and 1947; and if she did not what her main reasons were for not doing so—e.g., attraction of other work, dissatisfaction with midwifery, ill health, attainment of retiring age, or marriage. She is asked what are her additional qualifications, whether she was required to have a midwifery qualification for present post, who has employed her in the years the main ways in which she has used her midwifery qualification over those years, whether she worked in town or country and how many confinements she has attended yearly. Finally she is asked whether on the whole she is satisfied midwifery and if not why not.

This questionary, at first sight rather can be quickly answered by ringing certain opposite each question, as a covering letter and as soon as the answers have been sorted by the papers will be destroyed: they will thus be confidential. It is important to the country that questionaries should be carefully and fully by as large a proportion as possible of the re and doctors and hospital authorities who are in with midwives can give great help by encouraging midwife who hesitates to return her completed tionary. A pilot survey sent out to 275 mi produced a 60% response in a fortnight, but showed on the whole the practising rather than the non-p tended to reply. It would be unfortunate if the the main questionary showed this bias; perhaps the College of Midwives can influence non-practising grad to contribute their important share of information.

WILTSHIRE'S PROGRESS IN PART-TIME N

SINCE the part-time nursing scheme[1] was on April 18, the number of patients waiting for admission to Wiltshire county infirmaries has been reduced from 74 to 2. The response to the appeal for nurses been good: according to an interim report[2] of public-assistance committee, there are now 17 trained nurses, 8 enrolled assistant nurses, 32 nursing attendants, and 22 nursing orderlies at work in the infirmaries, as well as a further 16 part-time nurses in other hospitals. Four of the county's seven infirmaries are now fully staffed, and part-timers will be absorbed into the others as they come forward. Some matrons were outstandingly coöperative from the start, others perhaps less so, but the report notes that their general reception of the scheme has been satisfactory. Where the matron is convinced of the need for part-timers, both part-time and full-time staff settle down into a happy unit; and it is noteworthy that several people attracted by the part-time service have since taken up full-time nursing.

One remarkable outcome of the scheme deserves the notice of all authorities now arranging part-time services: Wiltshire is finding it possible to open more beds. At one hospital beds for the chronic sick are to be increased from 36 to 108; and at another a plan to provide dormitories for resident nurses is being given up, and the accommodation is to be converted for the use of 30 chronic sick, who will be nursed by non-resident part-timers.

AT a conference recently called by the United States Public Health Service it was recommended that a controlled study of B.C.G. vaccination should be undertaken in a community with a population of 100,000 or more. The conference concluded that B.C.G. "appears to confer increased resistance to tuberculosis" for the period covered by the studies presented, and that "there have been no proved cases of progressive disease from B.C.G. vaccination in human beings."

AT a meeting in London on July 23 Mr. Aneurin Bevan, Minister of Health, discussed with members of the 14 regional hospital boards some of the problems with which they will be faced. Mr. Bevan said that in his view it was best to bring the members together at the start, so that they might see themselves as part of an integrated service. Most of the boards, whose members give their services voluntarily, have already begun to meet and have advertised for their main officers.

[2] Second Interim Report on the Part-time Nursing Service. Wiltshire County Council.

ute to the work of the congress secretary, Capt. W. Geidt, and to Prof. E. G. T. Liddell, on whom, he d, had fallen many of the responsibilities of a president. fessor Liddell in a witty reply ascribed the success the congress to the vigour of its members: it was a e of Sherrington's "postinhibitory rebound," which d in this experiment been as marked as the period of ibition had been prolonged. The President displayed pecially bound copy of the presentation edition of the *tegrative Action of the Nervous System*, which was to sent to Sir Charles Sherrington as an affectionate bute from the congress. Throughout its meeting, deed, the congress had been informed by the great and ting influence of this veteran physiologist.

More important than the formal work of the congress, the opinion of many who enjoyed it, were the oppor- nities offered by the communal life in the colleges. is allowed frequent and personal discussions among ople who might otherwise have remained unknown to e another outside their writings. From the first, ese International Physiological Congresses have been imarily of this domestic nature and have owed their tality to it. They are gatherings devoted to the change of ideas about work for the most part actually progress and which will eventually be published. here are no published proceedings of the congress.

INTERNATIONAL CONGRESS FOR MICROBIOLOGY

COPENHAGEN, JULY 20–26

At the 4th International Congress for Microbiology r. Th. Madsen, the president, in welcoming over 000 members and associates, spoke of the difficulties arranging hotel accommodation, which necessitated ousing many delegates in hospitals, student hostels, nd private houses (all free of charge). Trouble was lso experienced in preparing abstracts of proceedings, rogrammes, and other printed material, because of a our-month printers' strike. Of more than twenty oreign countries that were represented, Britain probably ad the largest contingent, with France and Sweden unners-up. Many American scientists were unable to ravel because of transport difficulties; and there were o Russian delegates. It was a week of almost unbroken unshine and heat, the like of which had not been xperienced in Copenhagen for 10 years.

The discoverers of penicillin and streptomycin (who met for the first time accidentally at the Hotel Angleterre n Sunday morning) attracted much attention; and hroughout the week press photographers were almost btrusively active with their flashlight cameras snapping elebrities and their wives.

All the sectional meetings were held in the Rigsdagen (Parliament House), which allowed members to switch easily from one meeting to another, although there were still no answers to the problems of being in two places at the same time or of ventilating rooms kept continually darkened to allow the showing of lantern slides.

ANTIBIOTICS

The sections of most general medical interest were those devoted to antibiotics, medical and veterinary bacteriology, viruses, and immunology; and a considerable proportion of the contributions consisted in reviews of work already published but not yet sufficiently known in continental Europe.

The antibiotic section was accorded pride of place as regards accommodation, and undoubtedly attracted the largest audiences. Papers were given on the production, varieties, and mode of action of penicillin. E. F. Gale's discourse on the effect of penicillin in preventing the as[illegible] of glutamic acid by the staphylococcus being particularly interesting. Two outstanding contributions in this section were made by R. J. Dubos, of the Rockefeller Institute, and H. C. Hinshaw, of the Mayo Clinic. Dubos, after referring to his new media for the growth of the tubercle bacillus, discussed as-yet unpublished work on the genetic factors affecting the pathogenesis of experimental tuberculosis in mice, and the effect on the severity of the lesion of superimposed virus respiratory infection. "If," said Dubos, "the pathologist or the clinician points to the dissimilarity of tuberculosis in mice and men, the experimentalist can answer that the same is true of pneumonia and yellow fever; but what progress could have been made towards the control of these latter infections without the help of the mouse?"

Hinshaw described experimental and clinical trials of streptomycin, undertaken with W. H. Feldman; and he showed photographs of patients recovered and well after tuberculous meningitis. He emphasised that the action of streptomycin in tuberculosis is mainly suppressive, and that cures in miliary tuberculosis and in tuberculous meningitis are not common, particularly if these two manifestations occur together. The drug in their experience was practically free of toxicity, apart from the production of temporary vestibular disturbances.

A new approach to the control of virus infections was suggested by the experimental work of D. W. Woolley (U.S.A.), a blind scientist, who has been able to prevent multiplication of the influenza virus in the chick embryo by the use of apple pectin, a polysaccharide to which the virus is adsorbed in much the same way as it is to the red blood-cell.

BACTERIOLOGY

In the section on medical and veterinary bacteriology the subjects discussed were diphtheria, pertussis, streptococcal infections, tuberculosis, and brucellosis. J. W McLeod demonstrated the important part which the gravis strain plays in outbreaks of diphtheria, and showed that there might occur remarkable declines in the incidence of the infection after such epidemics. This point was supplemented by Charlotte Ruys (Holland), who, in an important investigation of epidemic diphtheria in Amsterdam during 1942–44, had found from Schick testing that there was much latent immunisation among the population at the end of the epidemic wave.

The papers on pertussis caused considerable discussion. R. Cruickshank reported that in day and residential nurseries rabbit or horse antibacterial-plus-antitoxic sera had a protective effect if given in the incubation period; Stuart Mudd described the Philadelphia work with agglutinogen as a skin test of susceptibility or resistance to pertussis. A. J. H. Tomlinson had found the complement-fixation test more reliable than the agglutination reaction for measuring the level of antibody at different periods after artificial immunisation; and H. Proom concluded from experimental work in mice that pertussis toxin may play some part in the pathogenesis of the infection.

In discussing the epidemiology of streptococcal infections in man, V. D. Allison and W. R. Maxted made a plea, which was sympathetically received, for an international committee on streptococcal grouping and typing; and later in the week a previously constituted Streptococcus Committee was resuscitated with Allison as secretary.

For the veterinarians there was a useful discussion on bovine mastitis, including classification, sources, and mode of spread of *Streptococcus agalactiæ*. In the brucellosis discussion I. F. Huddleston (U.S.A.) described a remarkable phenomenon of non-inhibitory dilutions of sulphonamides acting as bactericidal agent when sensitising antibody in high dilution was added.

INTERNATIONAL PHYSIOLOGICAL CONGRESS

OXFORD, JULY 21–25

THE 17th International Physiological Congress, which met in Oxford last week under the presidency of Sir HENRY DALE, O.M., was the third to be held in this country since the inception of the congresses in 1889, and the first since the Zürich congress of 1938. But for the war, it would have been held in Oxford in 1941. The previous congresses in this country were those at Cambridge in 1898 and at Edinburgh in 1923. The 1231 delegates, representing 38 countries (there were none from Germany and Japan) were accommodated in the colleges and elsewhere. They were received in the hall of Christ Church by Mr. H. A. MARQUAND, the Paymaster-General, on the evening of their arrival.

At the opening session in the Sheldonian theatre on the following morning the delegates were welcomed on behalf of their English-speaking colleagues by the President, and replies were made by Academician ORBELI (U.S.S.R.), Prof. B. A. HOUSSAY (Argentina), General R. K. S. LIM (China), and Prof. H. FREDERICQ (Belgium). The President read a message of greeting from Sir CHARLES SHERRINGTON. Each member had already been presented by the Physiological Society with a copy of a special edition of the *Integrative Action of the Nervous System*, with a newly written and masterly introduction by its author.

COMMUNICATIONS

The programme of scientific business included 361 communications, which were distributed among meetings held simultaneously in nine lecture theatres throughout the congress. Each lasted fifteen minutes and was followed by a discussion. There were 37 demonstrations of experimental methods and results and 22 of actual experiments, and 26 films. It will be appreciated, therefore, that no attempt can be made to describe the proceedings in detail.

A striking feature of the programme was the numerical preponderance of electrical and chemical studies of muscle and nerve, which together provided the main business for two of the lecture theatres. A. L. HODGKIN and A. F. HUXLEY's ingenious new modification of classical membrane theory to accommodate recent difficulties in explaining the origin of the action potential in nerve aroused particular interest. The communications of D. NACHMANSOHN and of others on acetylcholine metabolism, including some which dealt with the new anticholinesterase diisopropylfluorophosphate (D.F.P.), were a reminder that the electrical propagation of the impulse is inseparable from chemical events within the nerve.

The chemistry of the contractile process in muscle was the subject of several discussions, but these were overshadowed by a brilliant and informal lecture by A. SZENT-GYÖRGYI, in which he indicated the complex interrelationships between actomyosin, adenosine triphosphate, and electrolytes on which his theory of theory of muscular contraction rests. This evoked a very brisk discussion; the criticisms raised in no way lessened the attractiveness of the theory, whose full implications, scientific and clinical, have yet to be realised.

In renal physiology the main topics were the renal circulation and the mechanism of renal hypertension, and the osmotic regulation of water excretion. An elegant demonstration of the advantages of the combined physiological, histological, and radiological approach in the study of the renal vascular bed was given by J. TRUETA and his colleagues.

Interesting papers on blood dealt with its enzymatic capacities, particularly histaminolytic and fibrinolytic. In pregnancy the histaminase content increases with the duration of pregnancy and is disturbed in such conditions as toxæmia, hydatidiform mole, and abortion (A. AHLMARK, R. KAPELLER-ADLER). Spontaneous fibrinolytic activity occurs in surgical shock, trauma and other states (R. G. MACFARLANE, M. ROCHA E SILVA). Interesting results were reported on the use of the Hartridge-Roughton-Millikan rapid reaction technique in studies of the oxygenation of hæmoglobin, and on their mathematical treatment. W. JACOBSON and P. M. GOOD suggested, from a correlation of the fluorescence of anti-pernicious-anæmia extracts with their biological activity, that the anti-pernicious-anæmia factor has the nature of a pterin. A product of war-time activity which has a use in investigations of blood clotting are the silicone compounds which, applied to the surface of glass vessels, delay clotting for a matter of two hours (L. B. JAQUES).

E. WARBURG and A. T. HANSEN described a refined physical method for the continuous recording of arterial and other fluid pressures, which depends on variations in the capacity of a condenser attached to a needle small enough to be inserted into human blood-vessels. H. C. BAZETT measured the cooling effect of blood flowing in the venæ comites on blood flowing in the artery by means of needle thermocouples introduced into these vessels in man; this suggests an important mechanism of heat conservation. I. DE BURGH DALY showed a film of his method for the perfusion of a whole animal, with replacement of right and left ventricles by separate pumps: with this he provided the first demonstration of the existence of a pulmonary vasomotor control. At last we are seeing that in the pulmonary circulation there are reflex means of stabilisation of blood-pressure comparable to those of the systemic circulation, and afferents which may initiate them

Another outstanding film was that of W. R. HESS (Zürich), which, in conjunction with his demonstration of precision stereotaxic electrodes, displayed his methods and results of diencephalic stimulation and electrolytic injury in the cat. A variety of phasic movements, motor automatisms, and autonomic responses were elicited. Three other films had been produced by I.C.I., in collaboration with different teaching laboratories, for the education of medical students in this country. These fine films, in colour and with sound track, form a notable addition to the resources of the teacher of physiology.

For the benefit of the congress exhibitions had been arranged by the Bodleian Library, and by the Museum of the History of Science, of historic books and manuscripts and of historic scientific instruments.

THE PERSONAL SIDE

At a convocation of the university, held on the last day and attended by the whole Congress, the honorary degree of doctor of science was conferred on C. H. Best, H. S. Gasser, B. A. Houssay, A. Krogh, and A. Szent-Gyorgi. The ceremony was *not only* impressive but was notable for the classical felicities of the Deputy Public Orator, prominent among which was a reference to Gasser's work with the cathode ray oscillograph

> iam miramini virum qui Punico ingenio inter Pœnos ut electricos nervorum pulsus vi patefecit electrica, s fibras illas fistulosas fistula irradians oscillationum numeros occultos sensus vias suis sensibus est consecutus;

The closing session followed at once. It was unanimously decided to accept the invitation, extended most whole-heartedly on behalf of the Danish delegates by J. LUNDSGAARD *in a charming speech, to hold the* 18th congress in Copenhagen in 1950. The President ute to the work of the congress secretary, Capt. W. **Geidt**, and to Prof. E. G. T. **Liddell**, on whom, he d, had fallen many of the responsibilities of a president. fessor Liddell in a witty reply ascribed the success the congress to the vigour of its members: it was a e of Sherrington's "postinhibitory rebound," which d in this experiment been as marked as the period of ibition had been prolonged. The President displayed pecially bound copy of the presentation edition of the *tegrative Action of the Nervous System*, which was to sent to Sir Charles Sherrington as an affectionate bute from the congress. Throughout its meeting, leed, the congress had been informed by the great and ting influence of this veteran physiologist.

More important than the formal work of the congress, the opinion of many who enjoyed it, were the opportunities offered by the communal life in the colleges. is allowed frequent and personal discussions among ople who might otherwise have remained unknown to e another outside their writings. From the first, ese International Physiological Congresses have been imarily of this domestic nature and have owed their tality to it. They are gatherings devoted to the change of ideas about work for the most part actually progress and which will eventually be published. here are no published proceedings of the congress.

INTERNATIONAL CONGRESS FOR MICROBIOLOGY

COPENHAGEN, JULY 20–26

At the 4th International Congress for Microbiology Dr. **Th. Madsen**, the president, in welcoming over 000 members and associates, spoke of the difficulties n arranging hotel accommodation, which necessitated ousing many delegates in hospitals, student hostels, nd private houses (all free of charge). Trouble was lso experienced in preparing abstracts of proceedings, programmes, and other printed material, because of a our-month printers' strike. Of more than twenty oreign countries that were represented, Britain probably had the largest contingent, with France and Sweden unners-up. Many American scientists were unable to ravel because of transport difficulties; and there were o Russian delegates. It was a week of almost unbroken unshine and heat, the like of which had not been xperienced in Copenhagen for 10 years.

The discoverers of penicillin and streptomycin (who met for the first time accidentally at the Hotel Angleterre on Sunday morning) attracted much attention; and throughout the week press photographers were almost obtrusively active with their flashlight cameras snapping celebrities and their wives.

All the sectional meetings were held in the Rigsdagen (Parliament House), which allowed members to switch easily from one meeting to another, although there were still no answers to the problems of being in two places at the same time or of ventilating rooms kept continually darkened to allow the showing of lantern slides.

ANTIBIOTICS

The sections of most general medical interest were those devoted to antibiotics, medical and veterinary bacteriology, viruses, and immunology; and a considerable proportion of the contributions consisted in reviews of work already published but not yet sufficiently known in continental Europe.

The antibiotic section was accorded pride of place as regards accommodation, and undoubtedly attracted the largest audiences. Papers were given on the production, varieties, and mode of action of penicillin, E. F. **Gale**'s discourse on the effect of penicillin in preventing the assimilation of glutamic acid by the staphylococcus being particularly interesting. Two outstanding contributions in this section were made by R. J. **Dubos**, of the Rockefeller Institute, and H. C. **Hinshaw**, of the Mayo Clinic. **Dubos**, after referring to his new media for the growth of the tubercle bacillus, discussed as-yet unpublished work on the genetic factors affecting the pathogenesis of experimental tuberculosis in mice, and the effect on the severity of the lesion of superimposed virus respiratory infection. "If," said **Dubos**, "the pathologist or the clinician points to the dissimilarity of tuberculosis in mice and men, the experimentalist can answer that the same is true of pneumonia and yellow fever; but what progress could have been made towards the control of these latter infections without the help of the mouse?"

Hinshaw described experimental and clinical trials of streptomycin, undertaken with W. H. **Feldman**; and he showed photographs of patients recovered and well after tuberculous meningitis. He emphasised that the action of streptomycin in tuberculosis is mainly suppressive, and that cures in miliary tuberculosis and in tuberculous meningitis are not common, particularly if these two manifestations occur together. The drug in their experience was practically free of toxicity, apart from the production of temporary vestibular disturbances.

A new approach to the control of virus infections was suggested by the experimental work of D. W. **Woolley** (U.S.A.), a blind scientist, who has been able to prevent multiplication of the influenza virus in the chick embryo by the use of apple pectin, a polysaccharide to which the virus is adsorbed in much the same way as it is to the red blood-cell.

BACTERIOLOGY

In the section on medical and veterinary bacteriology the subjects discussed were diphtheria, pertussis, streptococcal infections, tuberculosis, and brucellosis. J. W **McLeod** demonstrated the important part which the gravis strain plays in outbreaks of diphtheria, and showed that there might occur remarkable declines in the incidence of the infection after such epidemics. This point was supplemented by **Charlotte Ruys** (Holland), who, in an important investigation of epidemic diphtheria in Amsterdam during 1942–44, had found from Schick testing that there was much latent immunisation among the population at the end of the epidemic wave.

The papers on pertussis caused considerable discussion. R. **Cruickshank** reported that in day and residential nurseries rabbit or horse antibacterial-plus-antitoxic sera had a protective effect if given in the incubation period; **Stuart Mudd** described the Philadelphia work with agglutinogen as a skin test of susceptibility or resistance to pertussis. A. J. H. **Tomlinson** had found the complement-fixation test more reliable than the agglutination reaction for measuring the level of antibody at different periods after artificial immunisation; and H. **Proom** concluded from experimental work in mice that pertussis toxin may play some part in the pathogenesis of the infection.

In discussing the epidemiology of streptococcal infections in man, V. D. **Allison** and W. R. **Maxted** made a plea, which was sympathetically received, for an international committee on streptococcal grouping and typing; and later in the week a previously constituted Streptococcus Committee was resuscitated with Allison as secretary.

For the veterinarians there was a useful discussion on bovine mastitis, including classification, sources, and mode of spread of *Streptococcus agalactiæ*. In the brucellosis discussion I. F. **Huddleston** (U.S.A.) described a remarkable phenomenon of non-inhibitory dilutions of sulphonamides acting as bactericidal agent when sensitising antibody in high dilution was added.

INTERNATIONAL PHYSIOLOGICAL CONGRESS

OXFORD, JULY 21–25

The 17th International Physiological Congress, which met in Oxford last week under the presidency of Sir Henry Dale, O.M., was the third to be held in this country since the inception of the congresses in 1889, and the first since the Zürich congress of 1938. But for the war, it would have been held in Oxford in 1941. The previous congresses in this country were those at Cambridge in 1898 and at Edinburgh in 1923. The 1231 delegates, representing 38 countries (there were none from Germany and Japan) were accommodated in the colleges and elsewhere. They were received in the hall of Christ Church by Mr. H. A. Marquand, the Paymaster-General, on the evening of their arrival.

At the opening session in the Sheldonian theatre on the following morning the delegates were welcomed on behalf of their English-speaking colleagues by the President, and replies were made by Academician Orbeli (U.S.S.R.), Prof. B. A. Houssay (Argentina), General R. K. S. Lim (China), and Prof. H. Fredericq (Belgium). The President read a message of greeting from Sir Charles Sherrington. Each member had already been presented by the Physiological Society with a copy of a special edition of the *Integrative Action of the Nervous System*, with a newly written and masterly introduction by its author.

COMMUNICATIONS

The programme of scientific business included 361 communications, which were distributed among meetings held simultaneously in nine lecture theatres throughout the congress. Each lasted fifteen minutes and was followed by a discussion. There were 37 demonstrations of experimental methods and results and 22 of actual experiments, and 26 films. It will be appreciated, therefore, that no attempt can be made to describe the proceedings in detail.

A striking feature of the programme was the numerical preponderance of electrical and chemical studies of muscle and nerve, which together provided the main business for two of the lecture theatres. A. L. Hodgkin and A. F. Huxley's ingenious new modification of classical membrane theory to accommodate recent difficulties in explaining the origin of the action potential in nerve aroused particular interest. The communications of D. Nachmansohn and of others on acetylcholine metabolism, including some which dealt with the new anticholinesterase diisopropylfluorophosphate (D.F.P.), were a reminder that the electrical propagation of the impulse is inseparable from chemical events within the nerve.

The chemistry of the contractile process in muscle was the subject of several discussions, but these were overshadowed by a brilliant and informal lecture by A. Szent-Györgyi, in which he indicated the complex interrelationships between actomyosin, adenosine triphosphate, and electrolytes on which his theory of theory of muscular contraction rests. This evoked a very brisk discussion; the criticisms raised in no way lessened the attractiveness of the theory, whose full implications, scientific and clinical, have yet to be realised.

In renal physiology the main topics were the renal circulation and the mechanism of renal hypertension, and the osmotic regulation of water excretion. An elegant demonstration of the advantages of the combined physiological, histological, and radiological approach in the study of the renal vascular bed was given by J. Trueta and his colleagues.

Interesting papers on blood dealt with its enzymatic capacities, particularly histaminolytic and fibrinolytic. In pregnancy the histaminase content increases with the duration of pregnancy and is disturbed in such conditions as toxæmia, hydatidiform mole, and abortion (A. Ahlmark, R. Kapeller-Adler). Spontaneous fibrinolytic activity occurs in surgical shock, trauma and other states (R. G. Macfarlane, M. Rocha e Silva). Interesting results were reported on the use of the Hartridge-Roughton-Millikan rapid reaction technique in studies of the oxygenation of hæmoglobin, and on their mathematical treatment. W. Jacobson and P. M. Good suggested, from a correlation of the fluorescence of anti-pernicious-anæmia extracts with their biological activity, that the anti-pernicious-anæmia factor has the nature of a pterin. A product of wartime activity which has a use in investigations of blood clotting are the silicone compounds which, applied to the surface of glass vessels, delay clotting for a matter of two hours (L. B. Jaques).

E. Warburg and A. T. Hansen described a refined physical method for the continuous recording of arterial and other fluid pressures, which depends on variations in the capacity of a condenser attached to a needle small enough to be inserted into human blood-vessels. H. C. Bazett measured the cooling effect of blood flowing in the venæ comites on blood flowing in the artery by means of needle thermocouples introduced into these vessels in man; this suggests an important mechanism of heat conservation. I. de Burgh Daly showed a film of his method for the perfusion of a whole animal, with replacement of right and left ventricles by separate pumps: with this he provided the first demonstration of the existence of a pulmonary vasomotor control. At last we are seeing that in the pulmonary circulation there are reflex means of stabilisation of blood-pressure comparable to those of the systemic circulation, and afferents which may initiate them.

Another outstanding film was that of W. R. Hess (Zürich), which, in conjunction with his demonstration of precision stereotaxic electrodes, displayed his method and results of diencephalic stimulation and electrolytic injury in the cat. A variety of phasic movements, motor automatisms, and autonomic responses were elicited. Three other films had been produced by I.C.I., in collaboration with different teaching laboratories, for the education of medical students in this country. These fine films, in colour and with sound track, form a notable addition to the resources of the teacher of physiology.

For the benefit of the congress exhibitions had been arranged by the Bodleian Library, and by the Museum of the History of Science, of historic books and manuscripts and of historic scientific instruments.

THE PERSONAL SIDE

At a convocation of the university, held on the last day and attended by the whole Congress, the honorary degree of doctor of science was conferred on C. H. Best, H. S. Gasser, B. A. Houssay, A. Krogh, and A. Szent-Györgi. The ceremony was not only impressive but was notable for the classical felicities of the Deputy Public Orator, prominent among which was a reference to Gasser's work with the cathode ray oscillograph:

> iam miramini virum qui Punico ingenio inter Pœnos ut electricos nervorum pulsus vi patefecit electrica; qui fibras illas fistulosas fistula irradians oscillationum mentis occultas sensus vias suis sensibus est consecutus;

The closing session followed at once. It was unanimously decided to accept the invitation, extended most wholeheartedly on behalf of the Danish delegates by E. Lundsgaard in a charming speech, to hold the 18th congress in Copenhagen in 1950. The President pa rried assistants; and an adequate capitation fee. With se there need be no direction and no control of sale l purchase. Dr. Dahne's motion was, however, carried.

HEALTH CENTRES

)r. G. H. BARENDT (Southampton) moved that the mcil should formulate plans for the construction, ffing, and functioning of health centres. Dr. A. LBOT ROGERS (council) pointed out that a committee l already been set up, under his chairmanship, to estigate all sorts of group practices and also single ctices. Between 100 and 200 practices were to be estigated; and the public's opinion of group practice s to be tested. Dr. DAIN emphasised that so far the nister's directives to local authorities on health centres ered only the earmarking of sites. The motion failed.

NOMINATION FOR STATUTORY BODIES

Dr. J. HALLAM (North Staffordshire), moving that the ofession's nominations to all statutory bodies under e new service should be approved by the Minister, id that of 7 nominees from his area for the regional spital board, only 3 had been accepted. Speakers om other areas confirmed Dr. Hallam's experience. r. F. M. ROSE (Preston) said that for each of the two gions covered by his branch council, 6 nominations d been made; and for each only 1 had been accepted. the South-west region, said Dr. S. NOY SCOTT lymouth), only 2 out of 6 nominees had been accepted. . N. STEVENS (West Suffolk) said that in his area the minee had been turned down, leaving West Suffolk thout representation on the regional board.

Dr. DAIN observed: "This is the sort of thing that ay happen to you unless you have proper control ranged." It was hoped that the difficulty would be lved in the amending Act. The association had, he lded, put up altogether 85 candidates, of whom 27 had en adopted. "If we should come to terms with the inister and there should be a service—which, I think, ems very doubtful—we must know which is the body e Minister will consult. If we are not free to choose ose who are to represent medical opinion on these mmittees, we are sold." For the selection of members r the committees it might be possible to set up a joint ody representing the association, the Royal Colleges, nd perhaps other bodies.

The motion was carried.

Dr. J. M. ALSTON (City) moved that general-practitioner epresentation must be assured on the various statutory odies set up under the Act; and an amendment was dded that the holding of part-time appointments with cal authorities should not debar from service on local ealth committees.

Dr. TALBOT ROGERS said that regardless of the inister's directive urging the appointment of doctors o the local health committees authorities were still orming committees without consulting the local medical ommittees. Speaking as a county-councillor, Dr. W. N. EAK (mid-Cheshire) said that his council had established small committee of 6–8 doctors who discussed medical atters before they reached the council and liaised etween the profession and council.

The amended City motion was carried.

MIDWIFERY SERVICES

Dr. R. POOTS (Stratford) moved that all registered ractitioners should be entitled to undertake domiciliary bstetrics under the Act; that ten years' experience of omiciliary obstetrics should be accepted as an adequate reliminary condition of entry to an examination for diploma in obstetrics; and that if necessary an ppropriate new diploma should be established.

Dr. W. B. A. LEWIS (Shropshire and mid-Wales) uggested that action should be taken by the Royal ollege of Obstetricians and Gynæcologists to enable loctors to practise midwifery without first obtaining heir diploma; while Dr. J. H. E. MOORE (Leeds) conended that the solution lay in the hands of the General Medical Council, which should ensure that undergraduate raining was sufficient to enable doctors to practise bstetrics. Dr. C. MACKIE (Worcester and Bromsgrove) ressed the country doctor's claim to postgraduate raining. Lord HORDER (Marylebone) claimed that the estriction on the practice of midwifery by qualified ractitioners represented infringement of a statutory privilege: "I believe we have been taken a little far from our principles in this matter."

Dr. DAIN said that the Negotiating Committee would require the removal from the Act of the Minister's prerogative to approve doctors' qualifications to practise midwifery. An agreement had, in fact, been reached; women were to have the right to be attended, if they wished, by a doctor of their own choosing who would, if necessary, attend the confinement; and a separate payment was to be made for this service. A similar position to that under the Scottish Act had thus been achieved. Every doctor could practise midwifery if he wished; but there were not enough domiciliary cases to provide suitable experience for all. Quite a number would elect not to engage in obstetric practice, so that there would be enough cases to supply the remainder with experience. Doctors seeking to engage in obstetric practice must, however, give evidence to a local medical committee of their past experience and their opportunity for continued experience; there was no insistence on diplomas.

The motion was carried by 106 votes to 91.

WHOLE-TIME MEDICAL OFFICERS

Dr. R. Forbes won the meeting's support for a Hendon motion that whole-time medical officers employed by central, regional, or local authorities should have the right of appeal to a suitably appointed committee when their appointment was terminated on grounds reflecting adversely on their professional reputation or procedure.

ROTA OF PRACTITIONERS

The meeting rejected a motion by Dr. G. DE SWIET (Paddington) that in the new service provision should be made for a rota of practitioners for duty at night and weekends, and during holidays and sickness. This was damned by Dr. DAHNE as "totalitarian planning."

FEES FOR LIFE-INSURANCE EXAMINATIONS

Dr. S. WAND, chairman of the council's general-practice committee, gained the meeting's support for an agreement with the life-insurance offices by which 10*s.* 6*d.* is to be paid for a short form of medical report, to be used where the amount of the policy does not exceed £300; £1 11*s.* 6*d* is to be paid for a medical examination and report where the amount of the policy exceeds £300; and £2 2*s.* is to be paid if the form required by the company is exceptionally extensive.

TELEPHONE MESSAGES

In reply to a West Suffolk motion, Dr. Wand said that the resumption of the G.P.O.'s telephone message service was impossible, at least in London, because of shortage of equipment. However, a robot attachment to the telephone was a possible alternative. When the doctor is out the robot will say: "This is the robot speaking. Dr. X is out. Can I do anything for you?" The answer is recorded on a cylinder, and the doctor, on his return, plays it back. The company owning this device was willing, said Dr. Wand, to fit and to service the robot for £80 if 50 doctors came forward.

"DOCTOR" SIGNS ON CARS

Dr. D. A. FERMONT (Kensington and Hammersmith) called for the abolition of "doctor" signs on cars. This was opposed by a speaker who had heard that even the sheep in narrow country lanes respected the sign. Nevertheless, the motion was carried.

CERTIFICATION

A motion calling for reduction in the number of certificates which doctors may be called on to sign was withdrawn when Dr. DAIN explained that the association had formed, in conjunction with the Ministry of Health, a small committee to examine the question. "We hope that before the start of any new service we shall have done something to solve the problem of certificates."

SCOPE OF GENERAL PRACTICE

Dr. J. A. L. VAUGHAN JONES (Leeds), moving that the council should resist any attempt to diminish the present scope of general practice, said that a wide outlook was essential to the practitioner, who should not be divested of all his responsibilities by compulsory diplomas and postgraduate courses.

Dr. O. C. CARTER (Bournemouth) held that there had been considerable inroads into the general practitioner's

Discussions in the virus section centred around poliomyelitis and influenza, but were considerably curtailed by the absence of many American contributors. Poliomyelitis was shown by J. R. PAUL (U.S.A.) to have changed in areas such as the United States and Scandinavia from an endemic to an epidemic infection, with at the same time a steady decrease in the proportion of clinical cases among children under 5 years of age. Outbreaks with a case-incidence as high as ten times that recorded in America occurred among American troops in North Africa, the Middle East, and the Far East, while the native adult in the same areas was rarely affected. It was therefore suggested that the disease may be endemic in subclinical form among native populations. The part played by the fly in the spread of the disease was discussed by A. B. SABIN (U.S.A.) and others; while J. H. S. GEAR, from epidemiological studies on poliomyelitis in South Africa, was convinced that close personal contact such as occurs in households was the most important factor in the spread of the infection. The possibilities of immunisation against poliomyelitis by formolised vaccine were discussed by S. GARD (Stockholm) and others.

Among the papers on virus respiratory infections, the work by the Common-Cold Unit at Salisbury, described by C. H. ANDREWES and F. FULTON, attracted particular attention. G. and W. HENLE (U.S.A.) described a new test for assaying the potency of influenza-virus vaccine, and also discussed the mode of infection of the cell by influenza virus as it occurs in the chick embryo.

IMMUNOLOGY

In the immunology section an outstanding contribution was that by M. B. LURIE (U.S.A.) on the mechanism of immunity to tuberculosis as exemplified by the phagocytic action of mononuclear cells from normal and immunised rabbits transplanted into the anterior eye-chamber of normal albino rabbits. V. MENKIN (U.S.A.) discussed the mechanism of leucocytosis in inflammation; and G. SHWARTZMAN (U.S.A.) illustrated with coloured lantern-slides the phenomenon of local tissue reactivity in the golden hamster. A. FELIX queried the virus nature of Vi bacteriophage, and E. HAMMARSTROM (Sweden) described an extended scheme for the phage typing of *Shigella sonnei*.

In other sections contributions that evoked favourable comment were M. DELBRÜCK'S (U.S.A.) work on the biochemical deficiencies of bacterial viruses; the discovery by K. M. SMITH of the transmission of a new plant virus by a biting beetle; and G. S. WILSON'S illustrations of the epidemiological value of phage typing in tracing sources of staphylococcal food poisoning. At the general meetings the two lectures of particular interest to medical men were F. C. BAWDEN'S review of the lessons to be learned from work on virus infection of plants, and S. A. WAKSMAN'S (U.S.A.) lecture on antibiotics.

At the plenary session on the last day resolutions were adopted for a new Bacterial Code, put forward by the Nomenclature Committee, in which rules are laid down to regularise priority in the naming of bacteria already described and for new bacteria; for enlargement of the Salmonella Subcommittee to include all the enterobacteriaceæ; and for a new committee on enteric phage typing, under the joint chairmanship of CRAIGIE and FELIX, with the Enteric Reference Laboratory at Colindale as the International Reference Laboratory.

And so, after meeting many old friends and making new ones, and after a week of almost unexampled hospitality by their Danish hosts, the delegates dispersed, to meet again, perhaps, in three years' time in Rio de Janeiro.

CONGRESS OF EXPERIMENTAL CYTOLOGY

THE 6th International Congress of Experimental Cytology, held in Stockholm between July 10 and 17, under the presidency of Prof. Johan Runnström, was attended by nearly 450 delegates from twenty-three countries.

Prof. A. Mirsky (U.S.A.) described his methods of isolating chromosomes and of investigating their chemical composition. He emphasised that his findings confirmed the results previously reported by Prof. T. Caspersson, of Stockholm.

Professor Astbury surveyed the possibilities of explaining biological processes in the cell with the aid of X-ray spectrography and the electron microscope.

Prof. René Dubos (U.S.A.) spoke on the membranes of bacteria; he pointed out that the composition of these membranes probably determines the pathogenicity of organisms.

Dr. Wyckoff (U.S.A.) described his investigations on viruses. With Dr. Williams he has worked out a new preparation technique for electron microscopy; the preparations to be examined are covered with a very thin film of metal molecules—gold or chrome—in which the virus particles stand out in a system of lights and shades, not unlike a moon landscape.

Dr. Humberto Fernández-Morán (Venezuela) showed pictures of brain tumours taken with the electron microscope of Prof. Manne Siegbahn, the Swedish Nobel prize winner. With an improved technique, it is now possible to discern details of dimensions down to 0·000002 mm.

Dr. Rittenberg and Dr. Shemin (U.S.A.) gave an account of recent experiments carried out with isotopes to observe the continuous building-up and destruction of body-tissues.

Prof. P. de Fonbrune (France) showed in a film how, by means of his micro-manipulator, the nucleus may be removed from a living cell and another inserted.

Mr. A. F. W. Hughes spoke on new methods of measuring the viscosity of intracellular fluid. He has succeeded in making connective-tissue cells, with a diameter of about 0·01 mm., "swallow" small iron bars about 0·001 mm. long. By means of a regularly swinging magnet the small bars are set in motion; and by measuring these "compass swings" it is possible to estimate the viscosity of the intracellular fluid.

BRITISH MEDICAL ASSOCIATION

THE REPRESENTATIVE MEETING

(Continued from p. 147)

Dr. S. F. L. DAHNE (Reading) proposed that the council should formulate a plan to end the maldistribution of practitioners, because the Minister had given this maldistribution as a reason for abolishing buying and selling of practices. He pointed out that for young men borrowing money to enter practice, the rate of interest could be reduced to 1% if each member of the profession subscribed 10*s*. 6*d*. a year, and to nil if each doctor gave one guinea; alternatively, if each doctor were to lend £50 the resulting fund would be large enough to supply on loan and without interest enough capital to enable these men to purchase their practices. Mr. Bevan had been reported as having said lately in Reading: "The profession is at last seeing reason and *beginning to dance to my tune.*" Perhaps because of this, the public was now assuming that the profession was abandoning its insistence on the right to buy and sell practices.

Dr. GUY DAIN, *chairman of council, said* that when a 100% service was introduced the problem of distribution would settle itself; for doctors would be attracted to the most thickly populated areas. The association was agreeable that special terms should be offered in rural districts; there was no need for direction. The doctor who borrowed money to enter practice was troubled less by the payment of interest than by the repayment of capital; and the loan was to him not a millstone but an incentive to do his best.

Dr. J. A. BROWN (Birmingham) suggested that the greatest needs were: premises for dealing with the greater flow of patients in the new service; houses for rried assistants: and an adequate capitation fee. With se there need be no direction and no control of sale l purchase. Dr. Dahne's motion was, however, carried.

HEALTH CENTRES

)r. G. H. BARENDT (Southampton) moved that the incil should formulate plans for the construction, ffing, and functioning of health centres. Dr. A. LBOT ROGERS (council) pointed out that a committee l already been set up, under his chairmanship, to estigate all sorts of group practices and also single ictices. Between 100 and 200 practices were to be estigated; and the public's opinion of group practice s to be tested. Dr. DAIN emphasised that so far the nister's directives to local authorities on health centres rered only the earmarking of sites. The motion failed.

NOMINATION FOR STATUTORY BODIES

Dr. J. HALLAM (North Staffordshire), moving that the ofession's nominations to all statutory bodies under e new service should be approved by the Minister, id that of 7 nominees from his area for the regional spital board, only 3 had been accepted. Speakers om other areas confirmed Dr. Hallam's experience. r. F. M. ROSE (Preston) said that for each of the two gions covered by his branch council, 6 nominations id been made; and for each only 1 had been accepted. the South-west region, said Dr. S. NOY SCOTT lymouth), only 2 out of 6 nominees had been accepted. r. N. STEVENS (West Suffolk) said that in his area the ominee had been turned down, leaving West Suffolk ithout representation on the regional board.

Dr. DAIN observed: "This is the sort of thing that ay happen to you unless you have proper control ranged." It was hoped that the difficulty would be ilved in the amending Act. The association had, he lded, put up altogether 85 candidates, of whom 27 had een adopted. "If we should come to terms with the linister and there should be a service—which, I think, ems very doubtful—we must know which is the body ie Minister will consult. If we are not free to choose iose who are to represent medical opinion on these ommittees, we are sold." For the selection of members or the committees it might be possible to set up a joint ody representing the association, the Royal Colleges, nd perhaps other bodies.

The motion was carried.

Dr. J. M. ALSTON (City) moved that general-practitioner epresentation must be assured on the various statutory odies set up under the Act; and an amendment was dded that the holding of part-time appointments with ocal authorities should not debar from service on local ealth committees.

Dr. TALBOT ROGERS said that regardless of the linister's directive urging the appointment of doctors o the local health committees authorities were still orming committees without consulting the local medical ommittees. Speaking as a county-councillor, Dr. W. N. EAK (mid-Cheshire) said that his council had established small committee of 6–8 doctors who discussed medical atters before they reached the council and liaised etween the profession and council.

The amended City motion was carried.

MIDWIFERY SERVICES

Dr. R. POOTS (Stratford) moved that all registered ractitioners should be entitled to undertake domiciliary bstetrics under the Act; that ten years' experience of lomiciliary obstetrics should be accepted as an adequate reliminary condition of entry to an examination for diploma in obstetrics: and that if necessary an ppropriate new diploma should be established.

Dr. W. B. A. LEWIS (Shropshire and mid-Wales) uggested that action should be taken by the Royal ollege of Obstetricians and Gynæcologists to enable loctors to practise midwifery without first obtaining heir diploma; while Dr. J. H. E. MOORE (Leeds) conended that the solution lay in the hands of the General Medical Council, which should ensure that undergraduate raining was sufficient to enable doctors to practise obstetrics. Dr. C. MACKIE (Worcester and Bromsgrove) ressed the country doctor's claim to postgraduate raining. Lord HORDER (Marylebone) claimed that the estriction on the practice of midwifery by qualified practitioners represented infringement of a statutory privilege: "I believe we have been taken a little far from our principles in this matter."

Dr. DAIN said that the Negotiating Committee would require the removal from the Act of the Minister's prerogative to approve doctors' qualifications to practise midwifery. An agreement had, in fact, been reached; women were to have the right to be attended, if they wished, by a doctor of their own choosing who would, if necessary, attend the confinement; and a separate payment was to be made for this service. A similar position to that under the Scottish Act had thus been achieved. Every doctor could practise midwifery if he wished; but there were not enough domiciliary cases to provide suitable experience for all. Quite a number would elect not to engage in obstetric practice, so that there would be enough cases to supply the remainder with experience. Doctors seeking to engage in obstetric practice must, however, give evidence to a local medical committee of their past experience and their opportunity for continued experience; there was no insistence on diplomas.

The motion was carried by 106 votes to 91.

WHOLE-TIME MEDICAL OFFICERS

Dr. R. FORBES won the meeting's support for a Hendon motion that whole-time medical officers employed by central, regional, or local authorities should have the right of appeal to a suitably appointed committee when their appointment was terminated on grounds reflecting adversely on their professional reputation or procedure.

ROTA OF PRACTITIONERS

The meeting rejected a motion by Dr. G. DE SWIET (Paddington) that in the new service provision should be made for a rota of practitioners for duty at night and weekends, and during holidays and sickness. This was damned by Dr. DAHNE as "totalitarian planning."

FEES FOR LIFE-INSURANCE EXAMINATIONS

Dr. S. WAND, chairman of the council's general-practice committee, gained the meeting's support for an agreement with the life-insurance offices by which 10*s*. 6*d*. is to be paid for a short form of medical report, to be used where the amount of the policy does not exceed £300; £1 11*s*. 6*d* is to be paid for a medical examination and report where the amount of the policy exceeds £300; and £2 2*s*. is to be paid if the form required by the company is exceptionally extensive.

TELEPHONE MESSAGES

In reply to a West Suffolk motion, Dr. Wand said that the resumption of the G.P.O.'s telephone message service was impossible, at least in London, because of shortage of equipment. However, a robot attachment to the telephone was a possible alternative. When the doctor is out the robot will say: "This is the robot speaking. Dr. X is out. Can I do anything for you?" The answer is recorded on a cylinder, and the doctor, on his return, plays it back. The company owning this device was willing, said Dr. Wand, to fit and to service the robot for £80 if 50 doctors came forward.

"DOCTOR" SIGNS ON CARS

Dr. D. A. FERMONT (Kensington and Hammersmith) called for the abolition of "doctor" signs on cars. This was opposed by a speaker who had heard that even the sheep in narrow country lanes respected the sign. Nevertheless, the motion was carried.

CERTIFICATION

A motion calling for reduction in the number of certificates which doctors may be called on to sign was withdrawn when Dr. DAIN explained that the association had formed, in conjunction with the Ministry of Health, a small committee to examine the question. "We hope that before the start of any new service we shall have done something to solve the problem of certificates."

SCOPE OF GENERAL PRACTICE

Dr. J. A. L. VAUGHAN JONES (Leeds), moving that the council should resist any attempt to diminish the present scope of general practice, said that a wide outlook was essential to the practitioner, who should not be divested of all his responsibilities by compulsory diplomas and postgraduate courses.

Dr. O. C. CARTER (Bournemouth) held that there had been considerable inroads into the general practitioner's responsibilities. He had spent some months on the Spens Committee; and a basic consideration had been that some of the best men should be persuaded to enter general practice. With further division of practice into watertight compartments the practitioner would, he suggested, *become just a filler-up of forms and a man* who refers patients to a specialist.

Dr. A. F. **Shirras** (Leeds) agreed that with all the pleasure going out of the work the best men would not be attracted to general practice. The doctor working in isolation was perhaps not going to trouble himself about retaining the disputed subjects; and possibly the aim should be to promote grouping or partnerships before the new service came into being. The motion was carried.

DOCTORS' CARS

Dr. W. **Gunn** (Greenwich and Deptford) put forward a motion expressing dissatisfaction with the arrangements by the association for obtaining doctors' cars. It was, he said, necessary to prove that a new car was essential and the present car unroadworthy; but, without being unroadworthy a car might be undependable. Dr. **Wand** pointed out that the motor trade is now free; there were no priorities as they had been known only a few months ago. There was a lag of at least 2–3 years before delivery; but, where the need was real the association's central office would probably be able to obtain a car at once or at least to get the applicant's name placed high on the waiting-list.

SHORTAGE OF NURSES

Dr. H. H. D. **Sutherland** (Kensington and Hammersmith) moved that the Minister of Health and the Secretary of State for Scotland should be asked to give urgent attention to the acute shortage of nurses. In London, he said, it was sometimes impossible to get grave and even urgent cases into hospital. Dr. J. B. W. **Rowe** (Harrow) held that the cause of the present impasse was shortage of student nurses. There were two main causes for this: (1) under the Rushcliffe scale the student nurse received in cash only 3¾*d.* per hour, or if she was working in a sanatorium 4¼*d.*; and (2) matrons tended to run nurses' hostels as a cross between a nunnery and an approved school.

Mr. **Weldon Watts** (Newcastle-on-Tyne) made a plea for private hospitals and nursing-homes; the largest nursing-home in Newcastle had, he said, lately been closed, entirely because of insufficient nurses. Another speaker contended that the student nurse must be paid at least enough to keep her—£90 per annum was a minimum. Dr. **Leak** suggested that nurses were being wasted in industry. Dr. C. K. **Cullen** (City) recalled that the General Nursing Council had refused a supplemental charter for tuberculosis nurses, and added: "It is time the council woke up from its world of fifty years ago." The nursing profession had been too regimented. "We don't want university graduates: we want people who can do the job." There must be a complete change of attitude; if the curriculum was too difficult, it must be modified.

Dr. C. F. **Mayne** (Plymouth) suggested that the trained nurse should be better paid; the part-time nurse, receiving 2*s.* 1*d.* an hour, had to pay 2*s.* 0*d.* an hour for a charwoman while she was away from home. The motion was carried.

Dr. **Talbot Rogers** advanced a rider calling for a special ad-hoc committee to make recommendations to the council. What was needed, he thought, was examination of all the evidence by a body which could take a wide view. Dr. A. C. E. **Breach** (Bromley), supporting this suggestion, said that not only nursing organisations but also probationers and even friends and relations of junior nurses should be approached to establish the origin of the present difficulty; the committee should also deal with the matter of domestic staffs.

Dr. R. **Kelson Ford** (Chelsea and Fulham) said that the number of nurses employed today was greater than before the war; yet the number of young women in the age-group from which recruits were drawn was smaller. There were simply not enough people to meet the demand; and the problem could be met only at the highest levels.

Dr. G. **MacFeat** (council) said that nurses tended to drift away from Scotland because of the better conditions in England. In his area part-time nurses, owing to their irregular attendance, had proved unsatisfactory. Nurses were, he added, being wasted in the social services where they often did only clerical work. "The training should not produce half-baked doctors instead of fully trained nurses"; and there should be some arrangement to cover the gap between leaving school and starting training.

Mr. R. L. **Newell** (council) also criticised the General Nursing Council—"that archaic body which is out of touch with present-day conditions." The association and the Ministry of Health had, however, done much; and since the Ministry's working party on nursing was soon to report he was opposed to the establishment of an ad-hoc committee.

A vote taken on this resulted in a tie; the chairman cast his vote in favour of the committee.

REMUNERATION FOR JUNIOR HOSPITAL POSTS

Dr. **Mayne** moved that, the present remuneration for junior hospital posts being inadequate, the association should formulate a scale of salaries for adoption by all hospitals. Mr. **Newell** replied that such a scale was being prepared; but the motion was carried.

REMUNERATION FOR PART-TIME EMPLOYMENT

The meeting approved the increased scales of payment for part-time work with local authorities; the increase on the 1938 figures, which is one of 40% for general practitioners and of 60% for specialists, has been in operation since last November.

CONSCRIPTION OF WOMEN DOCTORS

Dr. **Janet Aitken** won the meeting's support for a resolution passed by the Medical Women's Federation to the effect that the power to conscript doctors should be applied equally to men and women.

Annual Meeting

At the association's annual meeting on July 23 Sir **Hugh Lett**, the president, said that it had been decided that the affiliated and daughter associations in the Commonwealths should be invited to coöperate in the establishment of a British Commonwealth Medical Council. Each would appoint its own direct representatives, and meetings should be held in the principal centres overseas as well as is in London. It was also proposed to establish an Empire Medical Advisory Bureau at B.M.A. House, to advise and help those who came to this country from the Commonwealth and the Colonies for postgraduate or undergraduate study.

As a result of a world medical conference held in London last September on the initiation of the association, the World Medical Association came into being and this, he said, would hold its first annual meeting in Paris next September. The W.M.A. would be complementary to the W.H.O.; for while the W.H.O. would function at government level, the W.M.A. would function at professional level. The American Medical Association had, he added, just joined the W.M.A., which had already set on foot an inquiry into the trend of State policy in relation to medicine in different countries.

DENTAL HYGIENISTS

The Minister of Health, addressing the British Dental Students Association at Leeds on July 16, said that statements have been made that the Government intend to dilute the dental profession by employing ancillaries to undertake treatment which should properly be carried out by dentists. This was not true. The Teviot Committee, the majority of whose members were dentists, had recommended that a scheme for the training of dental hygienists should be initiated forthwith on such a scale as would provide an adequate test of their value. "The Government," said Mr. Bevan, "have accepted this recommendation. It is proposed to proceed with the experiment; but, until its results are known, no decision as to the future use of hygienists will be taken." There was no foundation for the suggestion that the Government intend to authorise dental technicians to undertake dental work which is at present the province of registered dentists. Technicians had a very important part to play in the new service but no alteration in the relations between dental technicians and dentists was contemplated.

In England Now

Running Commentary by Peripatetic Correspondents

THE Sheldonian Theatre was in summer mood, which tended to the bedels, when the closing session of the ysiological Congress was preceded by a convocation which honorary doctorates in science were conferred a distinguished pentarchy.

August in appearance and name, medium and bearded, iitening in age, Krogh, whose mien defied the Nazi olers he escaped, fulfilled our imagery of "a most ligent inquirer" whose "accuracy and elegance of ethod have led to those discoveries which have won m world-wide fame" and Nobel prize. Szent-Györgyi, 1o followed, as after Lind, seemed a veritable Puck, the discoverer of certain constituents of muscle, ranged spirally one around another," who well might dle the globe salving sailors "from the terror of scurvy"; d his later expression of thanks on behalf of the ngress reflected the goodfellow he was to conclude in rse! From the Rockefeller Institute and not from ensington Gardens came Herbert Spencer Gasser, ung in mind and long of limb, sized-companion of the rator and worthy American cousin. We looked to marvel at a great scientist who proceeded like 'a ief set to catch a thief' to detect those electrical anges that form a nerve impulse" with "an electrical vice" and "showed that each nerve-fibre sends its essages at a stable rate, but the smaller fibres more wly than the greater." Dr. B. A. Houssay "determined that he must live where the airs are good—Buenos ires—and in himself most certainly gives proof of the iceronian) theory that a man's life and character rrespond in quality to his native climate," said the rator; and this benign harmony was very evident in is short lively personage, hair dark in colour though te in middle age, who shared secrets with the conductor of the endocrine orchestra" to tell us that the agent exciting this disease (diabetes) in mankind, in the lower animals, is a hormone liberated by the aterior lobe of the pituitary gland itself." The young artner of "Frederick Banting, of immortal memory" ho shared "in those researches which discovered in ie pancreas of animals a substance of sovran aid to iabetics" was presented last. This fine and fair Canadian ousin was also comfortably cast for studies on the metaolism of fat. In Canada's wavy-navy, in war-time, "by adically decreasing the strain placed upon men so engaged e effected great improvements in submarine detection" nd he is the very embodiment of "a good messmate."

The visitors have gone home. To the far corners of ie earth they take their remembrances and our not considerable invisible exports—our good wishes and newed friendship.

* * *

Some years ago I received several cordial invitations go to the United States of America, but I didn't see ow I could possibly make both ends of the Atlantic eet, let alone visit both Coney Island and Hollywood. colleague however told me that the thing to do was work one's passage there and back as a ship's surgeon, nd my informant, who had done it himself, undertook introduce me to the appropriate shipping magnate. he introduction was effected after a big provincial inner, when the shipping magnate appeared to be omfortably in liquor and I was unusually tongue-tied. lind you, he may have always looked like that. And may I. I don't know. At any rate he seemed to emember me when I wrote to him, and replied by sking for a testimonial as a necessary formality emanded by his board. So I approached one of my igh-up friends in Harley Street, off whom I usually ake lunch when I am up in town, and asked him for a ood strong one. He doodled for a long while and then hrew down his pen saying, "Write your own damned estimonial and I'll sign it."

I tried hard to remember the nicest things that had ver been said about me, and couldn't recollect a thing. o I asked myself, "What's the very nicest thing you ould say of anybody?" I wrote it down carefully, ny high-up friend signed it, and I sent it off. Then for nonths I waited, wondering why I went on hearing nothing from the shipping company. The testimonial couldn't have been nicer. It ran: "This is to certify that of all my professional colleagues there is no-one with whom I would rather be shipwrecked on a desert island than with Dr. Peter Quince."

Eventually the penny dropped.

I imagine every G.P.'s wife is clamouring for a robot telephone. They know what it would mean, not only in time saved, but in the saving of emotional stress and the conservation of lipoids for exhausted suprarenals. A robot is undisturbed by pity, but it could get aggressive if it got stuck in the groove; "Dr. Blank is out, ring again in . . . again in . . . again in . . . again in . . ." How charming of it to be unmoved by rudeness, trivial calls, patronage, and pestiferousness; but its worst trick would surely be the "play-back" which says, in Lady Tweedlehampston's rasping tones, "Will the doctor ring Lady T. the moment he gets in?" Why stop at a robot phone? Why not a garage-door-opener, a front-door-answerer (the repertoire to include "Dr. Blank's away today; come again another day"). The robot phone could be fitted with an amplifier so that the patient could place the phone microphone below the left nipple with the preliminary words, "and here is the sound of my heart, doctor." In fact, the whole thing could probably be linked up with your electrocardiograph. This would save a lot of trouble. Oh yes, the G.P.'s wife would love to have one, but my wife is pretty certain that I wouldn't know we had it until I bumped against the thing in the hall. All this robot-mechanism will be controlled by a large switchboard so that by July, 1948, the kitchen will look like the cockpit of a modern bomber; then, on the Appointed Day, in one moment of careless rapture I shall press all the knobs at once, and Lo! we are nationalised.

* * *

The peripatetic correspondent writing about illegal immigrant ships (July 5) recalls an incident which occurred when one of the first of those ships arrived in port. There were a number of stretcher cases lined up waiting for the M.O., with as wide a variety of symptoms as one might find after searching through "Hutchison and Hunter." The M.O. was a dour Scot, who knew all there was to know about hysteria—and more besides. After examining the cases, he told a large proportion of them to get up and walk. The Tower of Babel does not hinder a determined Scot, and the effect was instantaneous. A corporal had watched the whole procedure with considerable admiration. "Blimey, sir," he said, "it's better than Lourdes."

* * *

What finally decided me to decline an offer of an administrative post was wood-turning.

At first I was tempted to give up my busy general practice and take a nice office job because it would give me plenty of time to do this; at present my hobby is like the carrot in front of the donkey's nose, for all I can hope to get in is about half an hour around midnight. But in a few minutes I had a vision of the house crowded to the front door with wooden bowls, plates, ash-trays, candlesticks, cups, disks, and twiddley bits, in all kinds of wood. Where would I get all this wood? It is impossible to buy it these days, and I am pleased to get a little bit of mahogany (which was apparently the centre-piece of a lavatory seat), or a heavy piece of jarrah which was left over from making a laboratory bench; once I had a piece of Canadian cedar which a dock pilot had treasured for years and reluctantly parted with, and another time a piece of a beam of a house which was beautifully dry and had the loveliest grain.

Kept in its right place all this is fun; it would spoil the joy to have too much of it.

* * *

You can't beat our old dog for perseverance. We watched him trying to get the marrow out of a knuckle bone the other day. First he stuck the open end in his mouth and sucked hard, but nothing happened because he hadn't drilled a hole in the other end first. I pointed this out to my wife, who said, "Leave the dog alone. He's doing his best and he's enjoying himself." Next he tried to stick his tongue inside the bone, but found that he couldn't reach far enough up. Several times it almost seemed as though he were trying to get himself into the marrow cavity. Eventually he gave up the tongue method and started the foot, or paw, method. Keeping one paw firmly fixed on the bone he tried to stick the other one inside. However, that also was doomed to failure because the external diameter of his paw was greater than the internal diameter of his bone. Just then my wife looked up, "Why don't you help the poor hound, instead of laughing at him?" she said. So I fished the marrow out with the end of a spoon from whence it disappeared rapidly down the dog's throat. I feel there is a moral in this somewhere.

Congresses may come and go; but the standard set by the Fifth International Congress of Pediatrics, held at the Waldorf Astoria Hotel in New York, will be difficult to rival. The meeting, at which 56 nations were represented, lasted officially from July 14 to 17, but the excitement began many days before that with the arrival of the first delegates from countries outside the United States. Pædiatricians who had known each other before the war met once more, and many new friendships were made before the conference began. These reunions and new associations were encouraged by the way in which Dr. Emmet Holt and his wife threw open their doors to delegates of all nationalities. They and the other organisers must have worked for months to make the congress a success.

The large number of exhibits and demonstrations arranged at the Waldorf by scientists, pædiatricians, and others working in the U.S.A. provided profitable entertainment for the whole four days. Practically all the papers and oral communications were given by the representatives of other countries. Monday (14th) was devoted to registration, exhibits, and an informal "smoker," and by the evening most people had sorted themselves out, decided what they wanted to see, and made contact with their friends. The congress was formally opened on Tuesday morning under the presidency of Dr. Henry F. Helmholz, and in the afternoon papers on nutrition were read by representatives from Great Britain, the Netherlands, South Africa, Denmark, Greece, and Norway, while delegates from other countries joined in the discussion. Communications could be made in English, French, Spanish, or German, and translations into all these languages could be heard through earphones. On Wednesday there were three short plenary sessions in the morning and less formal sectional meetings at the New York Academy of Medicine in the afternoon. In the evening we embarked on a six-hour steamer trip up the Hudson River. It had been a very warm day and the coolness and relaxation of this evening were much appreciated. Supper was provided on board and a great deal of shop was talked, but the beauties of the Hudson, Washington Bridge, and the lights of New York were not altogether neglected. On Thursday, after a day of plenary sessions, 1600 of us sat down to a banquet in the ball-room of the Waldorf Astoria, followed by speeches and then dancing. Most people went to bed feeling that they had not seen enough of the exhibits and demonstrations but they had had a wonderful week. After the official congress was over there were clinical demonstrations at the Babies Hospital, the Bellevue, Mt. Sinai, New York Hospital, and the Postgraduate Hospital, and on July 21 tours began to Boston, Chicago, Minneapolis, Rochester (Minn.), Detroit, and the Niagara Falls. Many arranged their own tours to see people or work which specially interested them.

Few of the delegates from Europe could have gone to the congress without financial assistance, and this was generously provided from funds collected by the organisers. I hope the people who provided this money will learn how much it was appreciated. The great value of such congresses lies in the chance they give people with kindred interests to get together, discuss their common problems, and hear about new work and new techniques. In New York the programmes were short enough to allow ample time for private talks, and the many minor conferences arranged by six or seven people were probably the most valuable part of the whole visit.

By the end of July most of the foreign delegates had left, some for lands where freedom and plenty have not yet returned, but all with a warm sense of gratitude to the pædiatricians of the United States.

Letters to the Editor

FATTY HERNIATION IN LOW BACK PAIN

SIR,—In your annotation last week you reported this subject and its recent confirmation by and Hench.[2] As to the accuracy of our c shall trust to future workers for further confirmation refutation.

You mention three difficulties in the way of acc work without reservation, and in the circumstances feel that some comment on these is called for.

(1) "Lack of anatomical evidence as to the of Copeman and Ackerman's basic fat pattern." is an academic point which is not relevant to our tion that fat lobules wherever they are situated become œdematous, and provided they are c within an indistensible fibrous covering or fascia, the result give rise to pain. Such pain moreover be temporarily abolished by dehydration of the cellular type.[3] If this increase in tension is herniation of the lobule will in certain cases occur, this may perpetuate the condition.

(2) "Subcutaneous fatty nodules are to be found over 50% of persons not complaining of backache" ourselves made this observation and suggested that abnormality which differentiated our nodules from painless type is the presence of the pathological non-inflammatory œdema which we demonstrated.[1]

(3) "These views conflict with those of . . . Burns Young, who believe that the prolapsed disk is the of most cases of persistent low back pain." The two distinguished orthopædic surgeons hold this can scarcely be considered as proof that the lesion cribed by us has no existence. We have never moreover that our lesion constitutes the cause of important proportion of cases of "fibrositis" of back—merely of those in which we have c demonstrated it by biopsy.

DENTAL CARIES

SIR,—The letter from Dr. Neumann, of New York in your issue of June 7 cannot be allowed to p unchallenged.

The premises with which Dr. Neumann begins letter are as follows:

1. "The teeth being part of the bony skeleton, it is able to suppose that they, like bone, react to such with demineralisation and atrophy."
2. "For various reasons these changes cannot readily demonstrated in teeth, by either radiography or analysis."

There is of course no doubt that dental caries is a associated with civilisation, but the theory that odontoporosis, as Dr. Neumann terms it, is the which leads to dental caries requires some exp

With regard to Dr. Neumann's first premise, the in dental caries is primarily upon the inorganic p of the enamel of the tooth, or possibly, according to workers, upon the organic matrix. It is the e therefore, that bears the brunt of the carious a The enamel is formed by the enamel organ, an epit structure derived from a downgrowth of the epithelium. After eruption, the enamel organ atrophied, no living cells with nuclei remain within enamel. There is no analogy between the reactions bone *and the reactions* of the *acellular* ect enamel. Osteoporosis in bones is of course about through the mechanism of osteoclasts. suggest that the processes of "demineralisation" bones and teeth are analogous, presumes either osteoporosis can obtain without osteoclasis or osteoclasts or similar cells in some way absorb erupted enamel; the latter phenomenon has never observed, and both theories are equally untenable.

The further premise that "for various reasons changes cannot readily be demonstrated in teeth, either radiography or chemical analysis," as a prelude

2. *Ibid*, p. 204.
3. *Lancet*, 1946, ii, 553.

development of the argument along less precise and entific lines. is curious.

Thewlis, working at the National Physical Labora-y, has shown that very fine differences in degree of cification can be demonstrated radiologically. Micro-emical analysis will determine fine differences in emical composition. Histology, though at times mittedly dangerous, at least would show the presence osteoclastic cells, should they be present.

Later in the letter, in order to sustain the argument, e idea of any connexion between fluorides and dental ies is dismissed. It must be pointed out, however, at while much is still unknown, research in this country, the United States, and elsewhere has at least proved yond dispute the connexion between high fluoride ake and low caries incidence. As I have already id, the connexion between civilised diet and dental ies is not in doubt; but Dr. Neumann's suggestion at the disease is due to disuse odontoporosis, based arguments which do not bear critical analysis, may most misleading.

London, W.1. ALEXANDER B. MACGREGOR.

HOSPITAL RECORDS

SIR,—Mr. Cotton's article of June 21 (p. 881) presents merous observations that will be of great value in ture hospital organisation, and it is most important that perience such as his should be available to guide others anning records.

I have attempted to plan a system which has only been ied on a much smaller scale; but it has been adapted to of practical value to the clinician and may therefore erit incorporation in a planned national system. It based on the Copeland-Chatterson Paramount Sorting stem, which has already been employed for medical cords in special departments but which I have adapted general use in all hospital departments (see figure). his has been achieved by using the Medical Research ouncil's classification of diseases.[1]

Essential particulars regarding the patient and clinical tes are summarised in the centre of the card. Coding the data is recorded by punching out the appropriate holes round the edge. If a needle is passed through the corresponding holes in a batch of cards all those punched will fall out and be sorted from those not punched.

Compiling a complex form regarding hospital patients for some central authority will be regarded as one of the most irritating features of a National Health Service. If the records were compiled on a card such as this the cards could be forwarded to a central bureau, the information coded there, and the cards returned for use at the hospital concerned. At a central bureau obviously a punch-card system with mechanical sorting would be employed, and it might be possible to transpose the records from a Copeland-Chatterson card to a punch card by mechanical means. The apparatus for mechanical sorting is elaborate and expensive and obviously will only be available at a few selected centres.

The return of the cards to the hospitals from whence they were sent would mean that the clinician had them at hand for his personal use. Instead of being obliged to fill in forms in which he had no interest (to put it mildly), he would compile a record card which would be always available for reference. If he was making an inquiry which involved searching through a large number of records he could avail himself of the facilities of mechanical sorting by means of the duplicate set of punch cards kept at the central bureau. Record cards compiled by a clinician who is interested in their value are going to afford much more accurate information than a form completed under compulsion and forwarded to an inaccessible Government department.

Such a system will be useful to the clinician in many ways. All cases of a certain disease can rapidly be traced and subdivided with regard to complications, symptoms, or age- and sex-incidence, while the relationship between occupation and disease can be studied both ways. Complex relationships can readily be studied—for example, the age-incidence of a particular complication occurring in a disease or a group of related diseases, or the incidence of different causes of a specific symptom at different ages. In practice the system is often useful in unexpected ways. Thus a rather unusual rash is seen which is difficult to classify, and perhaps is thus not properly coded. Later I meet a similar case and want to trace the first case for comparison. I cannot recollect

the patient's name or the main diagnosis, but I remember she was a girl of about 14 with scoliosis whom I saw about a year ago. On that information she could easily be traced.

The system has been tried for about a year in the children's department of the Cheltenham General Hospital, and it is hoped that some clinicians will give it a more extensive trial. The essential purpose of this letter, however, is to emphasise that the incorporation of some such system in the records of the National Health Service would add greatly to their efficiency and accuracy as well as being of practical help to the clinician in his daily work.

BATHING AND POLIOMYELITIS

SIR,—A striking omission from official advice on the control of infantile paralysis is specific reference to the danger inherent in the use of swimming-pools and in river bathing.

This is in striking contrast to public-health measures enforced in other countries. In Canada, for example, bathing establishments are all closed immediately a prevalence of poliomyelitis reveals itself—and this in a country where towns are widely separated and focal densities are much sparser than in Britain.

Unfortunately, it seems that we are on the brink of a widespread epidemic. It is generally believed that the causal virus is harboured predominantly in the intestine; and there is little doubt that, at the moment, there exists a considerable proportion of carriers.

The danger in bathing is not confined to the possibility of receiving the virus; muscular overstrain, fatigue, and chill provide, in bathing, an additional risk, since these may potentiate clinical attacks in cases where infection might otherwise have remained latent or abortive.

At this time of year, with children returning for school holidays, these considerations assume a very special importance.

London, W.1. MICHAEL ALBURY.

VITAMIN A IN LEUCOPLAKIA

SIR,—Last week's annotation leads me to say that in the past year I have used high dosage of vitamin A in a number of cases of so-called "leucoplakia vulvæ" with marked success in the relief of symptoms. My results are recorded in the 3rd edition of my book, *Diseases Affecting the Vulva*, which is now in the press.

The successful use by dermatologists of vitamin A in the treatment of various hyperkeratotic eruptions suggested to me that it might be effective for these vulval cases. I have given vitamin A in capsules or in drops by mouth only; I have not used hydrochloric acid but have occasionally prescribed an alkaline mixture half an hour before meals in cases with sluggish liver or gall-bladder complaints. One of the main difficulties of vitamin-A therapy in Great Britain is that concentrated preparations are in short supply and treatment may be interrupted in consequence.

For many years now I have been making a study of vulval cases of this type, and recently I have gained the impression that the numbers presenting themselves are increasing and that the type is more severe. Inquiry among these women has revealed that most of them are in the habit of surrendering the greater part of the rations which contain vitamin A to the male members or the children of their households. They themselves thus go short of vitamin A, and all declare how intensely they miss an adequate supply of fresh milk.

The term "leucoplakia" was originally suggested for whitish lesions occurring on mucous surfaces, to distinguish them from white-looking eruptions on the skin; the word is still used in this sense by dermatologists. The term "leucoplakia vulvæ" is used by gynæcologists not only for whitish eruptions on the inner or mucocutaneous surfaces of the vulva but for more widespread eruptions on the thighs, genitocrural furrows, and buttocks, and around the anus. The histology of this eruption is identical with that of lichen sclerosus—a variety of lichen planus. Lichen planus occurs on mucous surfaces and on the glabrous skin, and not infrequently the woman with a lichen-sclerosus eruption affecting the vulva and adjacent regions—i.e., what is termed "leucoplakia vulvæ"—has a lichen-planus eruption in the mouth and may have patches of lichen sclerosus at other sites remote from the vulva.

Your annotation speaks of "wide excision" as the most effective method of treatment. I agree that the results of this operation are often unsuccessful; and may I add, though I have seen a similar eruption on the scrotum; I have never heard it suggested that the scrotum should be excised for a non-malignant skin eruption.

London, W.1. ELIZABETH HUNT.

INTRAVENOUS IRON

SIR,—Your leading article of July 12 states that the hæmoglobin content of the circulating blood is 150 g. This is surely incorrect? If the volume of the circulating blood is taken to be 6 litres, and the hæmoglobin concentration 14·5 g. per 100 c.cm., the amount of hæmoglobin is of the order of 900 g.

London Hospital Medical College, E.1. J. C. MITCHELL.

*** We regret the mistake. The figure intended was 750 g.—ED. L.

Parliament

ON THE FLOOR OF THE HOUSE

ALL who were with the B.L.A. in Germany or with the B.A.O.R. in its earlier period must have known something of the currency deals, with cigarettes as a prime article of exchange, which have led to the loss of £58 million to the British taxpayer. They will recall the swapping of cigarettes for gold watches and jewellery, and the sale of ration bars of chocolate for a sum in marks which could be changed into English currency for perhaps 25s. In Paris soon after its liberation the friendly gift of a piece of ration soap to a lady would raise the gravest concern in the recipient, being roughly equivalent to a present of a string of pearls before 1939. The attack launched last week on the Secretary of State for War, Mr. Bellenger, served at least to place on record a part of the story as it affected Europe. But all over the world the war has degraded standards of personal conduct; and this degradation is part reason for the lack of confidence, the distrust, and the suspicion which haunts the body politic and the body economic in most countries. What is singular about the case brought against Mr. Bellenger is that in Great Britain such a loss of money is still regarded as a subject for the moving of what was practically a vote of no-confidence. We have kept our national resistance to black-market blandishments up to a relatively high level.

A Scots day including Scotch Education showed that when Sassenachs are absent, the representatives of the northern kingdom, of all parties, including the Communist, manage to agree to a very large extent among themselves. There is much to be said for self-government of areas which are geographically unified and where problems are not too vast for the ordinary mind to keep in clear relation to everyday experience.

The draft regulations on pensions and superannuation in the National Health service cover 87 pages. Introducing them, the Parliamentary Secretary to the Ministry of Health laid stress on "interchangeability" between one branch of the Service and another. It is intended that no-one shall be penalised by the new scheme if transferred from an existing scheme. And he gave a specific assurance that the principle of interchangeability as regards benefits, would be kept open so that other classes of persons engaged in medical or health work, besides those at present within the scope of the Act, can be included in the future.

MEDICUS, M.P.

FROM THE PRESS GALLERY

N.H.S. Superannuation Regulations

In the House of Commons on July 24 Mr. J. EDWARDS, Parliamentary Secretary to the Ministry of Health, asked approval for the draft National Health Service (Superannuation) Regulations, 1947. They had, he said, been fully discussed with all the representative associa-s concerned, and he was not aware of any opposition. scheme would cover all employees of regional boards, erning bodies of teaching hospitals, executive councils, other bodies set up under the Act, together with practitioners providing the general medical and tal services—probably a total of more than 300,000 ple. It was contributory, requiring contributions of of remuneration from the employee, and 8% from employer, except in the case of manual workers. re the rates were 5% and 6% respectively. The ployer's contribution would be paid by the Exchequer n the accounts of the hospital boards and other ies.

fter describing the benefits payable,[1] Mr. Edwards l that arrangements were made for interchange with federated superannuation scheme for nurses and the erated superannuation scheme for universities, and other interchanges. The object of the superannua- n scheme was to serve those who came under it— to tie them up in a system which might erect barriers en they wished to move from one employment to other. At the same time, the extensive interchange angements should help to promote wider experience ong the staffs.

The teething stages would set substantial problems. large number of persons would enter from local- ernment service, and there would be a considerable mber from voluntary hospitals who were now subject a variety of arrangements ranging down through ral expectations to nothing at all. The general n was to preserve existing rights as far as possible, and ensure that nobody would be worse off than before. ose who were now subject to the federated schemes uld have an option to continue on the same condition they wished, or to come into the new scheme and do at they liked with their policies. Those subject to her arrangements would be allowed to carry on with em if they could show that otherwise there would be due hardship. Any causes of dispute would be ferred to tribunals.

Voluntary-hospital officers of at least ten years' service ho had previously had expectations but no rights ould have the value of their expectations assessed relation to past service and, subject to Treasury pproval, a supplementary payment would be made on tirement in addition to what they earned in the new heme. In dealing with these provisions it was intended take a sympathetic and generous attitude. The heme also provided that all previous hospital service ould count for qualification purposes in the new scheme. his was of substantial benefit to those who now had no ghts; for though the service would not count in the lculation of benefit, it would mean that such an officer ight immediately become eligible for benefits—e.g., r the death annuity, which had a minimum of one ear's salary. A new division was to be set up in the inistry of Health to deal with the arrangements for terchange.

Mr. RICHARD LAW asked that a simple guide to the [illegible] ld be published. Regulation 38 (m), [illegible] a practitioner (doctor or dentist) who ad a contract with an ordinary life assurance company o opt out of the superannuation proposals: to help im pay his premiums the health authorities would pay him the share they would have paid for him under the scheme. This regulation, however, applied only if the practitioner joined the health service by the appointed day: if he did not do that, because he was rather suspicious of the service at first, he would lose this advan- tage. In Mr. Law's view, this introduced an element almost of blackmail; it was exercising very strong pressure on these practitioners to enter a service in which, it might be, they did not yet feel full confidence. In counting years of service for pension purposes the doctor was placed at a decided disadvantage by the fact that a manual worker could enter the service at the age of 18, whereas the doctor could not do so till he qualified, at perhaps 23, 24, or 25. Again, what would be the position of the practitioner who entered at 56? The retiring age was 65, and he did not begin to qualify for pension until he had had ten years' service. This appeared to be a real injustice. It could not be soundly argued that the Government, having paid compensation once, could not do so again by giving added years under the superannuation scheme. Nobody could say what the value of money would be in ten years' time, but it was likely to depreciate. That meant that the practitioner who was compensated for his practice in terms of today's money might find on retirement that his compensation was worth considerably less than at present.

Dr. HADEN GUEST hoped that the principle of inter- changeability would be maintained to enable different sectors of medical work to be brought in on an equal footing. At present there was no more than the founda- tion of a health service, which might be greatly and widely extended.

Colonel M. STODDART-SCOTT hoped that the Minister would interpret the regulations sympathetically and generously, for if a great National Health Service was to be built up the people who were to work in it must be contented and happy. It was quite easy for the Minister to coerce voluntary hospitals and to direct local authorities, but when it came to the personnel he must show a wise and "motherly" attitude and convince them that he was interested in every aspect of their welfare.

Sir WILLIAM DARLING called attention to regulation 33 which states that "an officer who is dismissed, resigns, or otherwise ceases to hold his employment in con- sequence of an offence of a fraudulent character . . . shall, if the Minister so directs, forfeit all claim." Who, he asked, was to be the judge of an offence? Was there to be an arbitrary decision by a medical superintendent or a hospital matron or somebody else?

Dr. H. B. MORGAN urged that care should be taken to see that health-service workers did not lose their right to superannuation through technicalities of legal procedure. If for health reasons a health-service worker was compelled to retire prematurely, superannuation should be given after a proper hearing and exchange of medical evidence and testimony. He knew of men who had been compulsorily retired on wrong medical diagnoses.

Mr. H. N. LINSTEAD said that there would be many people of one kind or another—not only doctors, but also radiographers, physiotherapists, and speech-therapists— who had been in private practice, and who, thinking that private practice was going to disappear, would wish to come into the public service at a late period of their lives. They would have had little hospital service on which to calculate for superannuation, and he hoped it might be found possible to extend in spirit hospital service to cover at least some of these older and experienced practitioners.

Mr. EDWARDS said that the Ministry of Health was preparing a simplified version of the regulations which would be available to everyone who wanted it. As to the restriction of claims as regards insurance policies, it would be difficult to have a different option in this respect from those permitted in other cases where the appointed day was the operative date. The Government could not go on indefinitely into the future and allow people to ask for these options. It had not been originally intended to have any such option at all, but it had been put in at the request of the British Medical Associa- tion representatives. Nor was it possible to single out doctors by adding years in respect of their training: a scheme of this kind could deal only with actual service. Doctors would now enter the service when they were qualified at the age of 23 or 24, and they could complete the full 40 years before they retired at 65, and thus could earn the full pension. The elderly practitioner, who was now relying on the value of his practice to provide for his retirement, would not be any worse off under these arrangements, and in addition he would earn some- thing in the national health scheme; but he could not expect some special benefit because he had entered late in life. Referring to Dr. Haden Guest's remarks on interchangeability, Mr. Edwards said that the Govern- ment wanted the scheme to be as broad in scope as they could make it, and if at any stage it was found to be restricted they would not hesitate to alter it. As to the loss of rights due to misconduct, presumably a disciplinary code would be worked out in collaboration with the people representing the new service, and there was no reason to suppose that the negotiating machinery would find it difficult to handle these cases. He felt that in this enormous scheme no real injustice had been done to any class of contributor, but if in the light of experience need was found for changes, the scheme would certainly be modified.

---

[1] See *Lancet*, July 5, p. 31.

The motion to approve the draft regulations was agreed to.

QUESTION TIME

Salaries of Veterinary Officers

Mr. S. HASTINGS asked the Minister of Agriculture how many appointments for veterinary surgeons in his Animal Health Division were unfilled; and what salaries were being offered for these posts.—Mr. T. WILLIAMS replied: There are about 140 vacancies on the permanent staff of which 75 are at present filled by temporary officers. These vacancies are in the basic grade for which the salary scale in the country is £520 for men of 25 rising to a maximum of £960. The salary is slightly higher for veterinary surgeons stationed in London and certain provincial cities.

Mr. HASTINGS: Does my right hon. friend regard this basic salary as sufficient considering the long training and the responsibility of the work involved?—Mr. WILLIAMS: My advisers are satisfied that these salary scales are regarded as satisfactory when compared with those of other professional and scientific civil servants.

In response to a further question by Sir E. GRAHAM-LITTLE, the Minister said that these salaries are substantially higher than those previously in operation.

Measles and Scarlet Fever in Scotland

Mr. W. ELLIOT asked the Secretary of State for Scotland what were the notifications and the deaths for measles and scarlet fever in each of the years from 1935 to 1946.—Mr. J. WESTWOOD replied: The following are the figures:

Year	Measles		Scarlet fever	
	Notifications	Deaths (all Scotland)	Notifications	Deaths
1935	7891	141	22,670	199
1936	30,981	610	18,320	172
1937	7543	119	20,493	123
1938	26,383	549	19,605	98
1939	3516	15	12,023	47
1940	26,125	262	8353	35
1941	4467	103	8760	26
1942	17,888	144	13,792	24
1943	13,601	88	14,722	22
1944	13,900	46	12,057	18
1945	12,714	89	11,654	15
1946	17,503	85	9774	5

Measles is not generally notifiable in Scotland but only in certain areas under local arrangements. About one-half of the 55 local health authorities have made such arrangements covering rather more than three-fifths of the population.

Botulism

In answer to a question from Mr. B. JANNER, Mr. A. BEVAN, Minister of Health, replied: There may be a risk of botulism from home-canned or home-bottled vegetables because the high steam pressure needed to ensure complete sterility during the canning process cannot ordinarily be applied in the home. Even this slight risk does not arise with home-canned or home-bottled fruit because of its acid content, or with beans preserved in salt. With commercially canned vegetables there has never been a reported case of botulism in this country and the risk is considered negligible.

Mental Defectives

Mr. S. SHEPHARD asked the Minister of Health how many persons who had been reported as mentally deficient were awaiting admission to an institution for treatment.—Mr. BEVAN replied: On Jan. 1 last, the latest date for which comprehensive statistics are available, the number was 3898.

Mentally Defective School-children

Mr. SHEPHARD also asked how many children of school age had been reported as mentally deficient and were still awaiting admission to an institution for treatment.—Mr. BEVAN: During 1946 the number of children reported under section 57 of the Education Act, 1944, was 4209. I regret that information is not available as to the number now awaiting admission to an institution.

Public Health

Vital Statistics for First Quarter of 1947

THE Registrar-General announces[1] that births were registered in England and Wales quarter ended March 31, representing a birth-rate 22·8 per 1000 total population. This is the birth-rate recorded for any March quarter since For the same quarter of 1946 the number of 181,220 with a rate of 17·1: for the December of 1946 it was 221,815 with a rate of 20·5. births totalled 12,286, or 5·1% of the total births tered, compared with 14,930, or 8·2%, in the same of 1946.

The following table compares the birth-rate quarter with the annual rate for each year from

RATE PER 1000 POPULATION (ENGLAND AND

Live births registered in ..	1938	1939	1940	1941	1942	1943	1944	1945	1
March quarter	15·3	15·0	14·8	14·3	15·3	16·6	17·4	16·9	17
Whole year ..	15·1	14·9	14·5	14·1	15·6	16·2	17·5	16·1	19

Deaths registered in the quarter were 181,933, a death-rate of 17·2 per 1000 compared with 14·7 for same quarter of 1946. Deaths of children under year numbered 12,502; the provisional infant-mo- *rate of 55 per 1000 related live births* was 11 per below the average rate for the first quarters of ten preceding years 1937–46.

The "natural increase" of population—i.e., excess of births over deaths in the quarter—was while the corresponding excess for the March of 1946 was 25,995.

There were 74,820 marriages during the quar this is 1009 more than the average for the same of the five years 1942–46.

Sickness Survey.—A new feature of the return section containing the results of a sample inquiry the prevalence of sickness during October, and December, 1946. Each month about 2900 people over 16 (so selected as to be representative of the population) were interviewed by workers for the Social Survey and questioned about their health during the previous two months. Similar sample inquiries have been undertaken for the Ministry of Health since 1944, but this is the first time the results have been published in this way. They are recorded in a series of tables showing the incidence and severity of illness and injury, the days of incapacity, and the number of medical consultations. The incidence of sickness in certain occupations and income groups is also shown.

In November, out of 2523 men interviewed, 1570 suffered from some illness or injury, and 1090 of them had consulted a doctor; out of 3182 women, 244 complained of illness and injury, and 1420 had a doctor. Colds and influenza caused far more days of incapacity in November than any other single illness, respiratory diseases and rheumatism being the next most disabling forms of sickness. Taking the three months as a whole, illness and injury of some kind was reported by 72·3%; there was an average loss of 1 day a month for all persons interviewed; 60 out of every 100 people reporting illness consulted a doctor, and there was an average of 27 consultations for every 100 illnesses recorded. Among housewives, illness injury was reported by 78·4%, compared with average of 72·3% for all people interviewed.

It is proposed to include the results of later inquiries in subsequent issues of the Registrar-General's Quarterly Return.

THE SECOND QUARTER

The *Registrar-General* has also published[2] for the June quarter. Live births numbered 235,0 stillbirths 5805, and deaths 118,169; the corresponding rates were 22·0, 0·54, and 11·1 per 1000 population.

2. Registrar-General's Weekly Return of Births and Deaths for the Week Ended July 19, 1947. H.M.S. 6*d*.

Food Poisoning

st week[1] an account was given of an outbreak of poisoning in 16 people who attended a luncheon party wyford, Hants, on July 12. Examination of ducks se eggs were used for a blancmange eaten at the lunch revealed that two had been infected with salmonella me time. It is thought likely that eggs from these s caused the outbreak and also the carrier state d in residents and domestic staff.

Poliomyelitis

the week ended July 19 there were 177 notifications liomyelitis in England and Wales. This is the highest e since compulsory notification was introduced in ; previously, the highest figure was 85, recorded he week ended Oct. 22, 1938. It is feared that the l in the past week has been still higher and that the has not yet been reached.

ases are widely scattered: they occurred in 36 differ- counties in the week ended July 19. The overall ure is therefore one of a large number of outbreaks, etimes spreading locally a little, rather than of an lemic spreading from one centre. The number of ifications rises regularly every year about this time; this year the rise came early and has been more rapid n ever before. In the past we have never suffered the ere epidemics which have been experienced in some er countries. In New York, for example, in 1916 re were 9023 notifications among a population of ut 5½ million: in England and Wales in 1938 there e 1480 notifications in a population of about 41 lion. The highest weekly figure for New York in 1916 s 1200, as against our latest figure of 177 for the whole England and Wales.

ince July 1, 135 patients suspected of having polio- elitis have been admitted to L.C.C. hospitals; but ny of these did not develop paralysis. Since July 22 admissions have ranged from 7 to 16 a day.

The spread of the disease is difficult to control because every case with obvious signs there are many re with mild and indefinite illness. There are also fectly healthy carriers who cannot be recognised by practicable method. In the opinion of the Ministry Health, the essential principles in control are there- e to secure the segregation of suspicious cases of ness occurring in the contacts of a definite case, and limit the aggregation of susceptible persons. The act application of measures to this end must be a atter for the discretion of the medical officer of health.

Smallpox

There have been no confirmed notifications of smallpox ring the past week. The disease was suspected but s eventually excluded in a member of the Polish settlement Corps who entered England from Holland July 10.

The 16-day surveillance of contacts of the last cases Bilston, Willenhall, and Barnsley has now ended thout further incident. There is a reasonable chance at the country is once again free from smallpox.

Infectious Disease in England and Wales

WEEK ENDED JULY 19

Notifications.—Smallpox, 1; scarlet fever, 1036; hooping-cough, 1931; diphtheria, 202; paratyphoid, ; typhoid, 10; measles (excluding rubella), 8400; eumonia (primary or influenzal), 306; cerebrospinal ver, 60; poliomyelitis, 177; polioencephalitis, 16; cephalitis lethargica, 3; dysentery, 56; puerperal rexia, 136; ophthalmia neonatorum, 75; relapsing ver, 1. No case of cholera, plague, or typhus was tified during the week.

The case of smallpox, which was imported, was notified at bury and Wilton.

Deaths.—In 126 great towns there were no deaths from teric fever, 1 (0) from scarlet fever, 1 (0) from diphtheria. (0) from measles, 7 (3) from whooping-cough, 60 (5) from iarrhoea and enteritis under two years, and 3 (0) from fluenza. The figures in parentheses are those for ondon itself.

The number of stillbirths notified during the week as 216 (corresponding to a rate of 22 per thousand otal births), including 15 in London.

Notes and News

"IRON LUNGS"

THE growing prevalence of poliomyelitis raises the question whether enough "iron lungs" are to be found in this country. It will be recalled that in 1938 Lord Nuffield offered this apparatus to hospitals in this and other countries; and these were distributed approximately as follows:

England, Wales, Scotland, Northern Ireland, and the Services	750
Canada	347
Australia	198
India and Burma	183
South Africa	46
Eire	40
New Zealand	33
Newfoundland	14
British hospitals in North Africa, China, Egypt, France, and South America	10
Elsewhere in the British Empire	134
	1735

Provided they are still in working order, there should thus be sufficient machines in this country to meet all needs, though hospitals may have to help each other out.

ROYAL NAVAL MEDICAL SERVICE

THE Admiralty announces that applications are invited to fill vacancies for medical officers in the Royal Navy. Candidates below the age of 28 years are preferred; they must be medically fit for service at sea and in any part of the world. No examination in professional subjects will be held, but applicants will be required to attend for interview by a selection board. Selected candidates will be entered initially for a period of four years' short service. Officers who leave the Service at the end of this time will be eligible for a gratuity of £600, tax-free. At the end of four years' short service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers on the permanent list are given opportunities for postgraduate study in order to obtain further qualifications and to specialise. Copies of the regulations for entry and conditions of service, including details of counting civil hospital time, and forms of application may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the deans of all medical schools.

University of Oxford

On July 25, as reported on pp. 182 and 187, the honorary degree of doctor of science was conferred on Dr. C. H. Best, F.R.S., Prof. H. S. Gasser, Prof. B. A. Houssay, Dr. August Krogh, and Dr. A. Szent-Györgyi. Next day the same degree was conferred on Dr. A. E. Barclay, honorary radiologist to the Nuffield Institute of Medical Research.

University of London

Mr. E. S. Horning, D.SC., has been appointed to the readership in experimental pathology tenable at the Royal Cancer Hospital, as from May 1, 1947.

Dr. Horning graduated B.A. at Oxford in 1924, M.SC. at Melbourne in 1925, and D.SC. in 1928. In 1925 he won a Victorian government research scholarship in biology at the University of Melbourne. In 1928 he was appointed cytologist to the Cancer Research Committee, University of Sydney. In 1930 he won a Rockefeller fellowship; and in 1931 and 1932 he held an honorary appointment on the staff of Washington University medical school. Between 1933 and 1937 he held a Beit fellowship at the Imperial Cancer Research Fund laboratories, and in 1938 he was appointed to the permanent scientific staff, where he remained until this year when he joined the staff of the Chester Beatty research institute of the Royal Cancer Hospital. He is the author of numerous original articles; a paper by him on the induction of glandular carcinomas of the prostate in mice appeared in these columns on Dec. 7 last year.

Dr. P. C. G. Garnham has been appointed to the university readership in medical parasitology tenable at the London School of Hygiene and Tropical Medicine.

Dr. Garnham studied medicine at St. Bartholomew's Hospital, qualifying M.B. Lond. in 1923. In 1924 he obtained a diploma in public health; and in 1928 he graduated M.D. Since 1925 he has served in the East African Medical Service, in which he became senior parasitologist in charge of the division of insect-borne diseases. He has made a special study of the epidemiology of malaria and of anopheles.

Dr. F. T. G. Prunty has been appointed to the university readership in chemical pathology tenable at St. Thomas's Hospital medical school, as from Oct. 1 next.

Dr. Prunty, who graduated M.A. at Cambridge in 1935, took his medical training at Cambridge and St. Thomas's Hospital, qualifying M.B. in 1941. In the same year he became M.R.C.P. After qualifying he was appointed house-physician at St. Thomas's Hospital. In 1944 he was awarded the Raymond Horton-Smith prize for his

---

[1] *Lancet*, July 26, p. 156.

Cambridge M.D. thesis. Since then he has been lecturer in chemical pathology at St. Thomas's Hospital; and in the past year he held a Rockefeller travelling fellowship and a research fellowship in medicine at Harvard University.

Dr. F. R. Selbie has been appointed to the university readership in bacteriology tenable at Middlesex Hospital medical school, as from Oct. 1 next.

Dr. Selbie is a graduate of Aberdeen, where he won the Alex Anderson scholarship. After qualifying as M.B., with first-class honours, in 1928, he held appointments at Aberdeen Royal Infirmary. He graduated M.A., and M.D., with highest honours, in 1932. For a time he was a scientific assistant to the Imperial Cancer Research Fund, and since 1939 has been assistant pathologist at the Bland-Sutton institute of pathology, Middlesex Hospital. He is a vice-president of the section of pathology of the Royal Society of Medicine.

Royal College of Physicians of Edinburgh

At a meeting of the college on July 15, with Dr. D. M. Lyon, the president, in the chair, the following were introduced and took their seats as fellows:

Joseph Bryant, T. E. Elliot, J. D. Allan, T. F. Rodger, and R. W. Craig.

The following elections were made:

Fellows.—John Craig, J. M. Rogan, J. M. Macfie, J. C. R. Greig, A. W. Wright, Neil Macmichael, Charles Cameron, and J. A. L. Gilbert.

Members.—R. W. B. Ellis, Simon Btesh, J. P. J. Paton, V. H. Wilson, A. J. Tinker, L. F. E. Lewis, P. L. E. Wood, J. H. Goonewardene, S. J. Fleishman, A. A. Williams, A. W. B. Edmunds, L. G. Woods, J. C. Williams, A. A. Guild, N. R. Stewart, jun., D. C. Haig, R. F. Robertson, and S. H. B. Blaikie.

Beit Memorial Fellowships

Sir Henry Dale, F.R.S., and Lord du Parcq have been elected trustees of the fund. The following awards have been made:

FOURTH-YEAR FELLOWSHIP

F. SANGER, B.SC. To study the structure of proteins with special reference to insulin: at the department of biochemistry, University of Cambridge.

JUNIOR FELLOWSHIPS

J. W. LITTLETON, M.SC. To study the purification and subsequent physicochemical characterisation of proteins involved in the coagulation of blood: at the Lister Institute of Preventive Medicine, London.

A. J. MARSHALL, B.SC. To study the humoral and nervous control of the decidual reaction of the mammalian uterus: at the department of zoology and comparative anatomy, University Museum, Oxford.

L. SILBERMAN, B.A., B.SC. To study the community costs of tuberculosis in terms of public-assistance and industrial outlay to patients and dependants, man-day wastage, and social-service provisions with special reference to the problems of reinstatement and revocation: at the University of Birmingham.

G. WEBER, M.D., PH.D. To investigate the reactions and behaviour of physiologically important proteins: at the Sir William Dunn School of Biochemistry, University of Cambridge.

Medical Society of the L.C.C. Service

A clinical meeting of this society will be held at the Northern Hospital, Winchmore Hill, N.21, on Thursday, August 7, at 2.30 P.M.

Removal of Control on Quinine

The Ministry of Supply has published an order ending from July 28 control over the supply in this country of quinine and its salts, and other products of cinchona bark.

Foot-and-Mouth Disease Committee

The Foot-and-Mouth Disease Research Committee has been reconstituted by the Minister of Agriculture and Fisheries with the following membership: Dr. A. N. Drury, F.R.S. (chairman); Dr. C. H. Andrewes, F.R.S.; Prof. S. P. Bedson, F.R.S.; Sir Daniel Cabot, M.R.C.V.S.; Mr. T. Dalling, M.R.C.V.S.; Mr. R. E. Glover, D.SC.; and Mr. Russell Greig, PH.D. Mr. I. A. Galloway, director of the Foot-and-Mouth Disease Research Station, and Mr. F. A. Eveleigh, of the Ministry of Agriculture, have been appointed secretaries to the committee.

Prof. R. R. Macintosh and Mr. A. Lawrence Abel will be among the lecturers in a course on the surgery of the digestive system, to be held in Barcelona between Sept. 29 and Oct. 7.

TELEPHONE MESSAGES.—Messrs. Finders Ltd., of 77, Dean Street, London, W.1, inform us that they operate a message service which may be useful to doctors. Messages are accepted by the firm (Tel.: Gerrard 9050) and delivered by telephone on request. The first dozen calls are free; thereafter the charge is 10s. per dozen calls or £3 per hundred calls.

Appointments

ABELES, F. M., M.D. Frankfurt, D.M.R.: radiologist, Oldchurch County Hospital, Romford.

BLAIR, E. J., M.D. Durh., M.R.C.P.: physician, New Cross Hospital, Wolverhampton.

BYRNE, A. A., M.C., L.R.C.P.I.: health officer, Malaya, Colonial Medical Service.

DUGDALE, H. R., M.B. Lpool, D.P.H.: M.O.H. and school M.O., Macclesfield.

GILLESPIE, HELEN, M.R.C.S.: psychiatrist, Essex County child guidance clinic, Chelmsford.

MABERLY, ALAN, M.B. Camb.: psychiatrist, Essex County child guidance clinic, Chelmsford.

PILKINGTON, F. E., M.B. Camb., M.R.C.P., D.P.M.: physician in psychological medicine, Prince of Wales's Hospital, Plymouth.

REID, D. A., M.B. Edin., F.R.C.S.E.: senior surgical officer, St. Margaret's Hospital, Epping.

Canadian Red Cross Memorial Hospital, Taplow:

ARDEN, G. P., M.B. Lond., F.R.C.S.: asst. orthopædic surgeon.

BELFRAGE, D. H., M.B. Camb.: anæsthetist.

BROWN, J. M., F.R.C.S.: surgeon.

CUDDIGAN, J. P., M.B. N.U.I., D.A.: anæsthetist.

DAWKINS, C. J. M., M.D. Camb., D.A.: anæsthetist.

FINLAISON, F. H. H., M.B. Camb., F.R.C.S., M.R.C.O.G.: obstetrician and gynæcologist.

HADLEY, G. D., M.D. Camb., M.R.C.P.: director of department of medicine.

MACONIE, A. C., M.B. Lond., F.R.C.S.: asst. ear, nose, and throat surgeon.

MARNHAM, RALPH, M.CHIR. Camb., F.R.C.S.: director of department of surgery.

MAXWELL, D. M. W., M.B. Edin., F.R.C.S.E., M.R.C.O.G.: obstetrician and gynæcologist.

PAYNE, R. V., M.CHIR. Camb., F.R.C.S.: surgeon.

PEACOCK, J. R., B.CHIR. Camb., F.R.C.S.: ear, nose, and throat surgeon.

RYCROFT, B. W., O.B.E., M.D. St. And., F.R.C.S., D.O.M.S.: ophthalmic surgeon.

SCOTT, F. E. T., M.B. Camb.: asst. pathologist.

SHACKLETON, R. P. W., M.R.C.S., D.A.: anæsthetist.

SHEPPARD, R. G., M.B. Lond., D.A.: anæsthetist.

SMILEY, W. K., M.B. St. And., D.O.M.S.: asst. ophthalmic surgeon.

WALLACE, H. J., M.D. Camb., M.R.C.P.: dermatologist.

WILLCOX, P. H., M.B. Camb., M.R.C.P.: physician.

Births, Marriages, and Deaths

BIRTHS

BENIANS.—On July 15, in London, the wife of Dr. R. G. Benians—a son.

BUTTLE.—On July 20, at Bognor, the wife of Dr. R. L. Buttle—a daughter.

CHALLIS.—On July 26, in London, the wife of Dr. A. W. H. Challis—a daughter.

CRAWSHAW.—On July 25, in London, the wife of Dr. George Crawshaw—a son.

DAWES.—On July 20, in London, the wife of Dr. A. J. A. Dawes—a son.

DE WYTT.—On July 8, in London, to Dr. Kathleen de Wytt (née Vickers), wife of Dr. William H. de Wytt—a daughter.

FAIRRIE.—On July 25, the wife of Dr. A. J. Fairrie—a son.

HALLINAN.—On July 25, the wife of Dr. T. C. Hallinan—a daughter.

HODGKIN.—On July 20, at Newcastle-on-Tyne, the wife of Dr. G. K. Hodgkin—a daughter.

KERSHAW.—On July 26, at Liverpool, to Dr. Mary Cowell, wife of Dr. W. E. Kershaw—a daughter.

REID.—On July 22, in London, the wife of Dr. D. D. Reid—a daughter.

RITCHIE.—On July 21, the wife of Dr. J. A. Ritchie—a son.

ROSS.—On July 20, at Newcastle-on-Tyne, the wife of Dr. G. M. Ross—a son.

SALKIELD.—On July 27, the wife of Dr. J. P. Salkield—a son.

SCOTT.—On July 23, at Milford on Sea, the wife of Major D. L. Scott, R.A.M.C.—a son.

SIDDONS.—On July 27, in London, the wife of Mr. A. H. M. Siddons, F.R.C.S.—a daughter.

SMALL.—On July 15, at Croydon, the wife of Dr. M. H. Small—a son.

WOLSKEL.—On July 14, in London, the wife of Dr. H. G. Wolskel, M.B.E.—a son.

MARRIAGES

FLINDT—SLOPER.—On July 19, at Semley, Michael Leighton Huntley Flindt, M.R.C.S., to Mary Pruen Sloper.

SHAW—HILLIER-HOLT.—On July 26, at Rotherfield, C. Stuart Shaw, M.B., to Jean Hillier-Holt.

DEATHS

BUCHANAN.—On July 23, at Glasgow, John Scouler Buchanan, M.B. Glasg.

FRY.—On July 10, Humphrey Francis Warren Fry, M.B. Bell., flight-lieutenant, R.A.F.

JUDSON.—On July 27, at Bournemouth, Joseph Edward Judson, M.R.C.S.

MUMMERY.—On July 20, in Jersey, Norman Howard Mummery, M.R.C.S., aged 70.

PHIPPS.—On July 23, in Jersey, George Constantine Phipps, L.R.C.P.I., lieut.-colonel, I.M.S., aged 45.

SENIOR.—On July 26, at Weston Green, Thames Ditton, Arthur Senior, M.B. Camb., D.P.H., aged 78.

STAWELL.—On July 26, at Falmouth, [illegible] de Salis Sta O.B.E., M.B. Camb., F.R.C.S., aged

SUBACUTE AND CHRONIC HEPATITIS

A. R. KELSALL

UNIVERSITY PROFESSOR

rom the Nuffield Department of Medicine, Radcliffe Infirmary, Oxford

THE standard descriptions of subacute hepatitis and rhosis in present textbooks are in some respects idequate, if not misleading, and many of the clinical, diological, and laboratory aids to diagnosis are not t widely known. As a result, there is still a tendency r these patients to be subjected to unnecessary and ngerous surgical interference, though in nearly all ses the diagnosis can be reached with certainty and ithout recourse to laparotomy by consideration of all he available data.

Since 1940, patients with liver disease have been bjected to intensive study in our department, chiefly om the biochemical aspect. Among the cases observed ring this period have been some 50 patients with ubacute or chronic hepatitis (cirrhosis), and the records 35 of these were sufficiently full to be suitable for a cent analysis in detail. A paper dealing with tests of ver function (Higgins et al. 1944) has already been ublished, besides a review of dietetic factors in the tiology and treatment of disorders of the liver (Witts 947). The present paper is primarily concerned with he clinical phenomena.

CLASSIFICATION

We do not propose to discuss in detail the histological hanges in the liver or the classification of cirrhosis. rom a study of our cases and of the relevant literaure we have formed the opinion that in hepatitis, as in nephritis, every gradation of chronicity exists, and the lack of agreement on this question among morbid anatomists has been mainly due to the necessity for drawing arbitrary lines in what is a continuous spectrum. The histological appearances of the livers in many of our fatal cases have corresponded to those described as toxic cirrhosis (Mallory 1911), chronic yellow atrophy of the liver (Bergstrand 1930), or subacute necrosis of the liver (Cullinan 1936); a few have shown the features of what would be generally accepted as the Laennec type of cirrhosis; while in the remainder there has been a coarsely nodular type of cirrhosis whose precise classification must remain a matter of individual opinion.

In view of these facts, we prefer to use the simple terms *subacute* and *chronic hepatitis*, meaning thereby a combination, in various proportions and distributions, of necrosis, cellular infiltration, fibrosis, and regeneration of liver cells. The *distinction* between subacute and chronic disease must again be purely arbitrary, and we have used the term "subacute" in cases whose estimated total duration of illness lies between two months and two years, cases of more than two years' duration being termed "chronic."

From the clinical point of view, patients with hepatitis fall into two fairly well-defined groups which may be further subdivided according to the following scheme; it should, however, be emphasised that the final clinical and pathological findings in the subacute and chronic cases in both groups may be identical.

Type I.—Onset with a clinically recognisable acute hepatitis, followed by:

(a) Rapid recovery.
(b) Rapid death ("acute yellow atrophy," "acute hepatic necrosis").
(c) A subacute stage with ultimate recovery.
(d) A subacute stage progressing to death.
(e) Chronic hepatitis.

In cases which become subacute or chronic, latent periods may occur; hence a further distinction can be made between those with continuous symptoms and those with intermittent symptoms.

Type II.—Onset insidious, progressing through a subacute stage to death within two years, or to chronic hepatitis. In this group, again, the disease may be latent for part or even for the whole of its course.

This classification is essentially similar to that of Bloomfield (1938), who was also struck by the resemblance to the natural history of nephritis, and it recalls the classification of nephritis proposed by Ellis (1942). One possible source of error was pointed out by Bloomfield: an acute exacerbation of a previously latent subacute or chronic hepatitis may be clinically indistinguishable from an initial acute hepatitis. A second difficulty is that in some patients a history is obtained of a previous attack of jaundice followed by many years of normal health; in such cases it is impossible to be certain whether there has been an unusually long latent period or whether a second attack of hepatitis has occurred.

ÆTIOLOGY

Initial Acute Hepatitis.—In most of our cases with an initial acute hepatitis the history suggested infective hepatitis, and in more than half a history of contact was obtained. We have also seen chronic hepatitis following acute hepatitis due to arsenotherapy and to carbontetrachloride poisoning. Subacute hepatitis may likewise follow homologous-serum jaundice (Turner et al. 1944).

Subacute and Chronic Hepatitis of Insidious Onset

In these cases obvious ætiological factors were less often discovered. Of the 35 patients studied in detail 18 are included under this heading.

One had been exposed to trichlorethylene for nine years while working in a laundry.

One had taken a bromide and arsenic mixture for epilepsy for many years and presented clear evidence of chronic arsenic poisoning.

One had a positive Wassermann reaction, but the necropsy appearances were not those of a syphilitic cirrhosis.

In one the diet had obviously been inadequate.

One, whose disease evidently started early in life, since splenomegaly was first found at the age of 7 years (present age 24), had had a brother who had died at the age of 16 years from ulcerative colitis and was said to have shown the lesions of hepatolenticular degeneration at necropsy. The patient presents no signs of neurological disease; he is, however, the Rh-positive son of a Rh-negative mother, and it may be that his cirrhosis is a sequel of unrecognised erythroblastosis fœtalis. Such a possibility has been suggested by Karsner (1943) and by Drummond and Watkins (1946).

In the remaining 13 cases there was no clue to the ætiology of the disease. We think it is worthy of special emphasis that not one of these patients was a chronic alcoholic. This is remarkable in view of the fact that in the United States chronic alcoholics still form slightly over half of the patients with cirrhosis (Ratnoff and Patek 1942, Fleming and Snell 1942). It seems that among hospital patients in this part of Britain at the present time chronic alcoholism as a factor in the causation of liver disease has practically disappeared.

The change in ætiological factors is accompanied by a difference in sex-incidence, to which we also wish to draw attention. Among our patients with acute hepatitis becoming subacute or chronic the sex-incidence was about equal, whereas in the group of patients with hepatitis of insidious onset females outnumbered males by nearly 3 to 1. This contrasts strongly with the series analysed by Fleming and Snell (1942), in which males outnumbered females by 3 to 1.

The age-incidence also showed a difference between the two groups, as follows:

Decade	1	2	3	4	5	6	7
Acute hepatitis becoming subacute or chronic	2	4	6	3	1	1	..
Subacute or chronic hepatitis of insidious onset	3	2	3	1	5	2	2

It will be seen that in the first group 15 out of 17 cases occurred in patients under the age of 40, whereas in the second group the number under 40 at the onset of symptoms was exactly equal to the number over 40.

The age-distribution is therefore more scattered, and the average is lower, than in alcoholic cirrhosis, which is essentially a disease of late middle life. Thus in our second group of patients the average age was 34·1 years at the onset of symptoms, 38·4 years at the time of first admission to hospital, and 41·4 years at death. Among the 200 cases studied by Fleming and Snell (1942), in 51% of which there was a history of alcoholism, the average age on admission to the Mayo Clinic was 50·4 years.

CLINICAL FEATURES

Acute Hepatitis Progressing through a Subacute Stage to Recovery

This clinical picture became very familiar to Service medical officers during the war. The initial stages of the disease are similar to those of other cases of acute hepatitis, and the anticipated improvement during the third or fourth week may occur, with apparent clinical recovery; the disease, however, has merely become latent, and a few days or several weeks later there is a return of jaundice and often of the associated gastro-intestinal symptoms; the liver may again become palpable and tender, and pyrexia may recur. After one or more such relapses, each of which may last days or weeks, final recovery takes place, though biochemical tests of liver function may remain abnormal after the disappearance of clinical symptoms and signs.

In other cases the jaundice lasts 8, 10, 12, or more weeks; during this period the patient may feel well and have a good appetite, but the liver often remains palpable and tender; occasionally attacks of undoubted biliary colic develop, and the gall-bladder may be felt. This may lead the unwary to diagnose extrahepatic obstructive jaundice and even to an unnecessary and hazardous laparotomy. Hæmorrhage from the gums, epistaxis, purpura, temporary ascites, and cutaneous spider nævi may arise. After a variable period, between two and four months, the jaundice starts to fade and recovery takes place; again the biochemical abnormalities often persist longer than the clinical manifestations.

Acute Hepatitis Progressing through a Subacute Stage to Death

The onset and initial course in this group are similar to those described for the patients who pass through a subacute stage to recovery. The subsequent progress, however, is increasingly unfavourable. Jaundice either continues without any change in its intensity, or fluctuates without ever disappearing entirely, or reappears at intervals. Ascites is common, and the fluid may be bloodstained. Pleural effusions may develop, though they are seldom large enough to be recognised clinically with certainty. Hæmorrhages into the skin and from mucosæ are common and may be the predominant symptom. Œsophageal varices may cause fatal hæmatemesis, splenic enlargement is common, and cutaneous spider nævi may be found. Intermittent pyrexia may develop. Death takes place from cholæmia or gastro-intestinal hæmorrhage, the former sometimes precipitated by intercurrent infection.

Acute Hepatitis becoming Chronic

Of our 35 patients 10 were included under this and all of them were still alive when contact was made with them. The illness lasted from two to ten years. Only 1 of the patients has had symptoms; in the other 9, latent periods have This suggests that patients in whom diffuse liver sufficient to cause clinical symptoms, progresses remission are unlikely to survive more than two Though 9 of the patients are leading active lives, or laboratory evidence of hepatic damage is still

After the initial acute hepatitis, which was with jaundice in all the cases, the course of the has been more variable in this group than in the ones. In 6 of the cases there have been several descences of jaundice, associated in 1 case with of pyrexia. Intermittent or transient ascites developed in 3 cases, and persistent ascites in 1 this patient is remarkable in that in thirty-two a paracentesis abdominis of 8–16 pints has been formed every seven to ten days (over 120 t an operation for obstructed umbilical hernia has necessary, yet she is still working full time as a nurse. Splenic enlargement, sometimes and cutaneous spider nævi have each occurred in the 10 patients. A palpable liver, skin and a hæmorrhagic tendency have each been found

Subacute and Chronic Hepatitis of Insidious Onset

This group comprises most of the patients so-called "cirrhosis of the liver," but the great in the duration and intensity of the process does seem to be generally appreciated. Progress may be relatively rapid, and death may occur within a year of the onset of symptoms; on the other hand, may be slow and insidious over many years, with minor or intermittent symptoms, until a final breakdown of liver function or the complications of advanced hypertension ensue; finally, there may be no clinical manifestations until death takes place either from a fatal complication, such as hæmorrhage from a ruptured œsophageal varix, or from some intercurrent illness.

Among our patients the duration of the disease from the onset of symptoms varied from 11 months to 11½ years, with an average of $4^1/_2$ years, in the 11 patients who have died; and from 3 years to 19 years, with an average of 9 years, in the 7 patients who are still alive, 4 of whom are leading normal lives. We wish to emphasise these figures, since to many the diagnosis of "cirrhosis of the liver" implies a prognosis which is considerably less favourable as regards duration of life than has been our experience; this is presumably due to the recent diminution in chronic alcoholism as a factor in the genesis of the disease, and to previous difficulty in making the diagnosis before the terminal stages.

The clinical features of these cases were very variable but tended to fall into patterns which are on the whole well known, and we do not propose to consider them in detail. The following symptoms and signs were found most often, in every conceivable combination and in this order of frequency: palpable liver; ascites (intermittent more often than continuous); splenic enlargement; jaundice (much more often intermittent than continuous); dyspepsia, particularly discomfort or pain under the right costal margin, intolerance of fried or greasy food, and flatulence; pigmentation; intermittent pyrexia; cutaneous spider nævi; gastro-intestinal hæmorrhage from œsophageal varices; and other hæmorrhagic phenomena (purpura, epistaxis, and bleeding from the gums).

DIAGNOSIS OF SUBACUTE AND CHRONIC HEPATITIS

A review of our cases shows the great advances which have been made of recent years in t osis ute and chronic hepatitis. The difficulty of making diagnosis with certainty ten to twenty years ago e appreciated by reference to the paper by Cullinan): of the 20 cases of subacute hepatic necrosis ted by him exploratory laparotomy had been rmed in 12, with 7 postoperative deaths. Similarly, (1931), in a review of 399 cases of cirrhosis seen at Mayo Clinic in six years, reported that in 135 of the liver disease was discovered for the first time parotomy. In the present series, apart from patients hom laparotomy was deliberately performed for ectomy or for relief of an obstructed umbilical ia, exploration has not been necessary for the nosis except in 2 cases, neither of which had been by a physician before operation.

he diagnosis of subacute or chronic hepatitis following e hepatitis should not prove difficult, provided that occurrence is appreciated. Persistent ill health, cially if associated with recurrent or continuous dice, a hæmorrhagic tendency, a palpable liver, or enlarged spleen, following an illness in which initial rexia or gastro-intestinal disturbance was followed aundice, should arouse strong suspicion of progressive atic damage.

ubacute or chronic hepatitis of insidious onset should considered in the differential diagnosis of any patient h splenomegaly, jaundice, persistent dyspepsia, a norrhagic tendency, or pigmentation, as well as with more dramatic and familiar symptoms such as ites and hæmatemesis. The relative frequency of mentation, pyrexia, and cutaneous spider nævi is thy of note. The pigmentation is a rather muddy wn and is often patchy, but has not been seen in the uth; skin biopsy in 2 cases showed that the pigment s melanin. The pyrexia is usually low-grade and ermittent, but occasionally the temperature rises to °F, apart from intercurrent infection; in 2 of our es this phenomenon led to erroneous diagnoses of nical malaria and of recrudescence of subphrenic ppuration. The spider nævus, if present, provides luable confirmatory evidence of hepatic damage, ugh Bean (1945), in a detailed account of these eresting structures, has pointed out that they may be n in pregnancy, hypovitaminosis B, and sometimes normal people. They are found particularly on the per part of the body and consist of a coiled central tery with radiating branches, appearing to the naked e as a small circular patch of erythema with a central, en pulsatile, bright red spot. The rarity of a caput dusæ, a sign still accorded a prominent place in some xtbooks, should be stressed; it was seen in only 2 of r patients.

Pleural effusion is a common terminal event in subacute d chronic hepatitis. Bilateral effusions were found in and right-sided effusions in 2, of our 13 cases which me to necropsy: in only 4 of them, however, were e effusions large enough to be detected clinically. ven when bilateral effusions are present, the amount fluid is often much greater on the right side, and a inical diagnosis of bilateral effusion was made in only patient. Occasionally, pleural effusion develops as a tem- rary event, and more rarely still is found in the absence ascites. No evidence of underlying infection was found these cases; the pleural fluids were always sterile, tubercle bacilli were found in them, and no evidence tuberculosis was found at necropsy.

Recent work on prothrombin deficiency in liver disease as perhaps tended to obscure the fact that other echanisms are often concerned in the hæmorrhagic ndency in these patients. Evidence of capillary bnormality, shown by a prolonged bleeding-time or positive tourniquet test, and moderate degrees of hrombocytopenia were found on one or more occasions in about a third of the patients with purpura or mucosal hæmorrhages.

Biochemical investigations provide valuable evidence in the diagnosis of subacute and chronic hepatitis, and in assessing the activity of the disease. This aspect has already been dealt with by Higgins et al. (1944), and we shall merely recapitulate that in most cases a combination of plasma-bilirubin, alkaline-phosphatase, and protein estimations will give as much information as can be obtained from more elaborate tests, though a lævulose-tolerance test in addition may sometimes be helpful. In subacute and chronic hepatitis slight or moderate elevation of bilirubin and phosphatase levels, diminution of albumin level, and rise in globulin level may form a distinctive pattern which is virtually pathognomonic. It must be emphasised, however, that any one of these tests may give normal results in liver disease, or abnormal results in diseases of other organs; a combination of tests is therefore essential, and the practice of attempting to diagnose the presence or absence of hepatic damage on the basis of a single biochemical investigation cannot be too strongly condemned.

Radiology may also be useful in the diagnosis of subacute and chronic hepatitis. Though the possibility of demonstrating œsophageal varices by a barium swallow was first described by Wolf (1928) and an entire chapter is devoted to the subject by Buckstein (1940) on radiology of the alimentary tract, this method is still not so widely known as it might be.

The patient is examined in the horizontal position, and in this hospital a thick barium paste is used, though Buckstein (1940) recommends a mixture of equal parts of barium and water. The paste travels more slowly through the œsophagus but may compress and obscure lesser degrees of varicosity of the veins. The mixture is not so liable to mask varices but often travels through the œsophagus too fast for satisfactory films to be taken.

If varices are present, the films may show irregularity of contour of the lower œsophagus, with abnormally prominent mucosal folds or circumscribed rounded defects.

Of 22 patients in whom this investigation was performed, varices were demonstrated in 6. A negative barium swallow, however, does not exclude the presence of varices; in one patient a radiogram seven weeks before death did not show varices which were revealed at necropsy, and in another patient a barium swallow was reported as negative though œsophagoscopy two weeks later showed eleven varicosities.

The value of radiology in assessing the size of the liver and spleen is also considerable, and minor degrees of splenic enlargement, insufficient to render the organ palpable, can often be demonstrated in this way (Dell and Klinefelter 1946), especially if a barium meal is given and the patient is examined in the horizontal position; the failure of the stomach to fall back into the left loin, together with any displacement or indentation of its wall, is thereby revealed.

In the presence of ascites the laparoscope is a useful diagnostic weapon.

We have no personal experience of aspiration-biopsy of the liver, but there seems little doubt that it will be increasingly used to elucidate difficult cases.

DISCUSSION

Our experience suggests that the type of cirrhosis seen most commonly in this country today is essentially different from the "alcoholic cirrhosis" which forms the basis for textbook descriptions and still appears to be common in the United States. Since alcohol per se has never been convincingly shown to cause hepatic damage (Moon 1934), though it can apparently intensify the damage caused by deficient or unbalanced diets (Bollman 1938, Lillie et al. 1941), "alcoholic cirrhosis" is presumably due to the dietary deficiencies so common in the chronic alcoholic, and may thus be comparable to the cirrhosis found so often among the malnourished populations of Asia and Africa. The types of cirrhosis which we now encounter, however, are in nearly all cases the result either of an initial infective or chemical hepatitis which has become chronic, or of insidious liver damage of unknown cause.

Whether subclinical or non-icteric attacks of infective hepatitis, such as were observed during the war among large military communities, are in some cases the starting-point for progressive hepatic damage, and whether the latter is due to a local vicious circle of malnutrition within the liver, are problems about which it is tempting but profitless to speculate. The fact remains that cirrhosis, in the Oxford area at any rate, is considerably commoner in women than in men, and that alcohol no longer ranks as an important ætiological factor. Recognition of this change in the incidence and type of hepatic cirrhosis, combined with knowledge of the diagnostic assistance now provided by biochemical and radiological investigation, should lead to earlier diagnosis and thus to the chance of more successful treatment.

SUMMARY

Some 50 cases of subacute and chronic hepatitis have been studied during the past six years, and the records of 35 of these have recently been analysed in detail. The present paper records briefly the results of this study.

The cases can be divided into those in which an initial acute hepatitis, due to virus infection or to chemical poisoning, becomes subacute or chronic; and those in which subacute or chronic hepatitis originates insidiously. In the latter group women outnumber men by three to one, chronic alcoholism has not been an ætiological factor, and in most cases the cause of the disease is quite obscure. The final clinical and pathological features in the two groups may be indistinguishable, and periods of latency are common.

The commonest symptoms and signs are a palpable liver, ascites, splenic enlargement, jaundice, dyspepsia, pyrexia, spider nævi, gastro-intestinal bleeding from œsophageal varices, and other hæmorrhagic phenomena. Ascites and jaundice are more commonly intermittent than continuous. The caput Medusæ occurs but rarely. Pleural effusions are often found at necropsy, and are occasionally large enough to be recognised clinically, especially on the right side. They are usually, but not invariably, associated with ascites.

Attention is drawn to the assistance in diagnosis which can be obtained from biochemical and radiological investigation.

We are indebted to our colleagues in the departments of clinical biochemistry and radiology for much help in the investigation of these patients.

ELECTRONARCOSIS

A NEW TREATMENT OF SCHIZOPHRENIA

A. SPENCER PATERSON
M.D. Edin., F.R.C.P.E., M.R.C.P., Dipl. Psych.
PHYSICIAN IN CHARGE OF THE DEPARTMENT OF PSYCHIATRY AND LECTURER IN THE MEDICAL SCHOOL, WEST LONDON HOSPITAL

W. LIDDELL MILLIGAN
M.D. Glasg.
DEPUTY PHYSICIAN-SUPERINTENDENT, ST. JAMES' HOSPITAL, PORTSMOUTH

IN 1902 a French physician called Leduc produced a narcotic-like state in rabbits and dogs by applying a unidirectional pulse current (Leduc 1902). Later he had a current applied in this way to himself and though he was not unconscious he was in a dream-like state and unable to move. In 1907 the Parisian surgeon Tuffier performed an operation on a patient rendered unconscious by similar means (Tuffier and Jardry 1907).

At Pasadena, California, Frostig et al. (1944) have found that electronarcosis differs from chemical narcosis in that the narcotic action of the current depends on its stimulating effect. The metabolism of the brain is reduced in chemical narcosis but remains practically unchanged during electronarcosis. Any current capable of stimulating the central nervous system could be used to produce narcosis. The stimulation, however, must be prolonged. For this reason either a pulsating or an alternating current is effective, whereas a direct current is not. The machine used gave a current of constant intensity, because changes in the resistance of the organism were automatically compensated by a special device. It was found advisable to give a relatively strong current to begin with (300 mA of a 60-cycle alternating current), to make the animal unconscious from the start.

After a brief period in which the legs were actively flexed, the animal's muscles became atonic for a few seconds, and thereafter it developed a strong extensor spasm in the legs, with opisthotonus. The condition resembled decerebrate rigidity. Respiration was arrested for the entire period, and the heart was momentarily inhibited.

After the first 30 sec. one of two syndromes might develop. These were described as the narcotic and hyperkinetic types. In the narcotic type, after some gasping respiration, the animal lay quietly, with occasional sporadic clonic twitches. It was generally necessary to increase the current by 5 mA every 1/4 min.; otherwise the animal tended to wake up. If the current were decreased by 20 mA catalepsy developed.

In the hyperkinetic type the animal kept trying to right itself with violent and incoördinated movements.

It was found, however, that if at the beginning of electronarcosis the strong initial current was kept up for 30 sec. the narcotic syndrome was more likely to develop.

In no case did examination of the brain after death reveal any irreversible changes.

Electronarcosis was also produced in 9 patients who had shown severe symptoms of dementia præcox for over four years. The initial dose was somewhat lower, 150–250 mA, and this was maintained for 30 sec., after which it was decreased to 45–90 mA, when respiration started again. It was found that, if the current were slowly increased by 5 mA when the patient showed signs of coming out of the narcosis, the condition could be kept up for half an hour in many cases. Some patients, however, tended to wake up after so short a period as 7 min. The symptoms in man were a mixture of narcosis and hyperkinesis, tending more to the former.

A further publication from the same school (Tiet et al. 1946) described the results t in zophrenic patients. They again used the high current 30 sec. and they applied the lesser current for another min. It did not appear to be of any value to prolong treatment beyond that limit. The period of 7 min. chosen because it was the minimum within which a ient might come out of the narcotic state, despite ease of current up to 120 mA or more.

A NEW ELECTRONARCOSIS APPARATUS

n July, 1946, one of us (A. S. P.) approached Mr. G. F. itter, M.I.E.E., and Mr. A. I. Rich, and they devised Shotter-Rich electronarcosis apparatus (see figure). s measures $8\times8^1/_2\times14^3/_4$ in. and weighs only 33 lb. : apparatus is designed to meet the following uirements:

1) It must be reliable, easily worked, and proof against possibility of an accidental shock, either to the patient the operator.

2) It should be easily portable.

3) Since the resistance of the living organism decreases idly with the application of the current, the predetermined ensity of current should be kept constant by means of a nce which automatically compensates for any change of istance. Even if the patient's resistance should fall to o, there should not be any considerable increase in the rent applied.

4) It should be possible for the operator easily to control current from zero to maximum, preferably by a rotary itrol device.

The Shotter-Rich electronarcosis apparatus consists of primary circuit which is connected to the 230/240 -cycle supply mains. The connexion to the mains this case 240 volts a.c.) is through a 3-core flexible ble.* The "patient circuit" is isolated from the ains by a transformer.

An entirely novel method, however, is used in this achine to obtain a constant current without the use of ermionic valves, and consequently there is no difficulty ith self-oscillation or the possibility of an increase of e "patient current" through faults in the apparatus. he constant current is made possible by electromagnetic eans in a specially designed circuit of proved reliability. he output current does not vary by more than a very nall percentage from the selected value, whatever may the resistance of the "patient circuit."

The current can be varied between zero and maximum the rotary device.

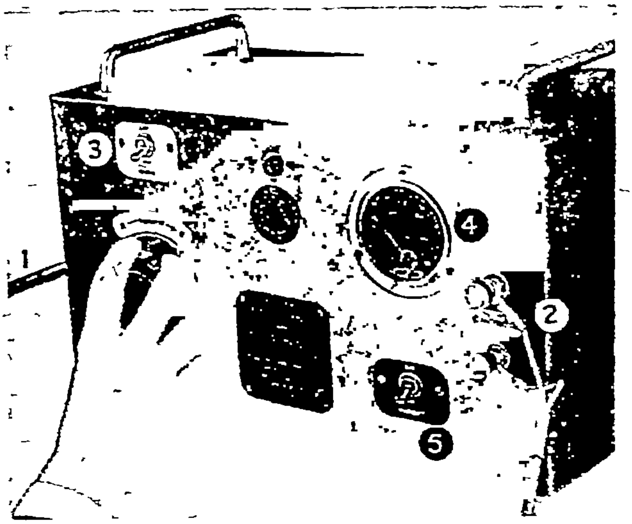
An ammeter calibrated in milliamps is used to measure e treatment current and is always in circuit. It is sed for pre-setting the value of the current and indicates e intensity of the current being passed through the atient.

There is a protective arrangement of neon lamps inside e apparatus. If the resistance of the patient should ach a high value, either through poor contact between ectrodes and patient or through any disconnexion at a rminal, these protective lamps light up. All the component parts have been fully tested at 2000 volts to rule ut any failure of insulation.

TECHNIQUE OF ELECTRONARCOSIS THERAPY

reparation of Patient

Each patient should be subjected to a thorough hysical examination, with special reference to the irculatory and respiratory systems. An electrocardiogram and a radiogram of the chest are highly desirable. f there is any hint of a previous convulsive disorder, an lectro-encephalogram should be taken. The thoracic nd lumbar spines should also be radiographed. Especilly in cases with any hint of memory impairment, full loses of vitamin-B complex should be given for some lays beforehand.



Apparatus for inducing electronarcosis: (1) cable to mains; (2) terminals of "patient circuit"; (3) mains switch; (4) ammeter; (5) "patient circuit" switch.

Before the actual treatment the patient's stomach and bladder must be empty. Other precautions are taken as with electric convulsive therapy. Women's hair-pins and clips are removed. The teeth are examined and dentures removed. Lipstick, rouge, and nail varnish are not permissible as they hinder the recognition of cyanosis.

A quick-acting barbiturate may be given before the treatment—e.g., seconal gr. 3–$4^1/_2$—or in excited patients up to gr. $7^1/_2$ sodium amytal intravenously. The patient is given atropine gr. $^1/_{75}$ half an hour before treatment. Alternatively, morphine gr. $^1/_4$ and hyoscine gr. $^1/_{150}$ may be given three-quarters of an hour before. This tends to prevent any apprehension. These sedatives hinder the development of unpleasant reflexes, such as undue cardiac inhibition, but in many cases they are unnecessary.

The patient should be on a fairly rigid bed, with a firm pillow or sandbag under the 4th, 5th, and 6th dorsal vertebræ. The tonic spasm, however, is not so strong as in electric convulsion therapy, and it is likely that no fractures will be recorded in this treatment.

An ordinary gag of tubing surrounded by gauze 10 in. long by $^1/_2$ in. thick will suffice, but many will prefer to have a special type of gag made (cf. Andratschke et al. 1946). At Pasadena they use two piles of 4-tongue blades wrapped in gauze which are placed between the molars on each side to prevent biting of the tongue. They also use an airway and two soft rubber catheters, one fixed within the airway, through which saliva is sucked out by an apparatus attached to a running tap. If the nasal passages are thoroughly cleansed first, these procedures will probably not be found necessary.

A cylinder of 5% carbon dioxide in oxygen is provided which should be able to run for at least 7 min. A gas flow of about 15 litres a min. is usually sufficient.

A stethoscope, a sphygmomanometer, and an emergency stimulant, such as 'Coramine,' are advisable. We have also found it useful on occasion to insert about 5 in. of a lubricated rubber tube through one nostril. This is transfixed with a safety-pin to prevent it from slipping. The distant end will then be in the nasopharynx. This sometimes greatly facilitates respiration.

Fitting of Electrodes

A special headgear has been constructed. It consists of a headband of flexible rubber $1^1/_2$ in. broad widening to 4 in. over the occiput. This prevents the band from slipping upwards or downwards. It is fastened at one side by means of two adjustable metal clips made of nickel-silver. The two electrodes are about 2 in. square, with rounded edges and rounded corners. The terminals have non-detachable heads and slotted holes and are self-locking. They are made of nickel-plated copper and are non-corrosive. They are easily slipped off the band for cleaning. Saline pads are applied to the electrodes, which are placed over the temples. The patients find the band quite comfortable. As in electric convulsion therapy, care should be taken that none of the contact jelly is continuous between the two electrodes, as this will lessen the current passing through the skull.

---

* The apparatus is manufactured and marketed by Messrs. Rich & Bundy, 18, New Road, Ponders End, Middlesex.

Treatment

The apparatus is connected to the mains by plugging in the cable (see figure). Wires run from the terminals on the machine to electrodes applied to the patient's temples. After the "patient circuit" has been completed, the mains switch is turned on. This enables the operator to adjust the ammeter to a predetermined value, generally 160 mA. The treatment is actually started by switching on the patient switch, causing an immediate tonic flexion of the extremities. After about 10 sec. there is a momentary atonia, followed by extension of the legs and opisthotonus. The pulse disappears for a few seconds, after which the heart beats slowly and irregularly. Respiration is arrested, and the patient may become cyanosed.

After 30 sec. the second stage of treatment is begun. The current is reduced to 65 mA. A few clonic twitches occur, lasting a few seconds. Within 15 sec. the patient gasps and thereafter breathes regularly. If the onset of respiration is delayed, or if it is difficult, the rubber tubing may be inserted into the nose. Carbon dioxide and oxygen are administered as soon as the current is reduced. It is usual to increase the current by about 5 mA every 15 sec.

There is a convenient physiological sign which indicates that the correct level of narcosis has been attained. This is a mild inspiratory stridor, which appears in most cases. It is thought to be caused by a moderate apposition of the vocal cords. If the narcosis is too deep, the vocal cords may become too much approximated, and respiration becomes difficult. If the stridor disappears, the patient is probably beginning to come out of the narcosis. In either case the correct level can be attained by raising or lowering the current. In the second stage a current of 140 mA should not be exceeded, as a second onset of severe tonic spasm may ensue.

COMPARISON WITH ELECTRIC CONVULSION THERAPY

Electronarcosis is more scientific, because a current of known intensity is passed through the patient. In electric convulsion therapy, on the other hand, the actual current passed through the patient is not known, as the patient's resistance drops during the passage of the current, and these changes are not compensated for electronarcosis.

In electronarcosis the current is not so strong as in convulsion therapy and usually does not cause a [illegible] at 160 mA, even given for several seconds. When strong current is reduced, the clonic movements relatively feeble and last only a few seconds.

In electric convulsion therapy the hypotonic period between initial flexion and extensor rigidity may last up to $^1/_2$ min., but it is only momentary in electronarcosis.

In electric convulsion therapy the extensor rigidity continues for some time after the current has been switched off, but in electronarcosis it ceases when the high current is decreased at the end of $^1/_2$ min. In [illegible] cases respiration starts again about $^1/_2$ min. after the current has been switched on, for in electronarcosis the duration of the strong current is the same as that of the fit in electric convulsion therapy—i.e., $^1/_2$ min.

RESULTS OF TREATMENT

Twenty patients have been treated by us. They were all schizophrenics who were definitely hallucinated. They had been ill for various periods and it is as yet too early to assess the results of treatment.

American pioneers in this method of treating schizophrenia have reported results as good as those obtained by insulin-coma therapy (Tietz et al. 1946). Though we were not particularly hopeful when starting this treatment, the results so far attained are distinctly promising. In every case the hallucinations have disappeared, for some weeks at least, and in some instances the recoveries have been most striking after only a month's treatment.

DISCUSSION

Until recently insulin-coma therapy has proved the most successful treatment of early schizophrenia. It has, however, certain disadvantages. Owing to shortage of staff, only a limited number of hospitals can use it. It requires a team of specially trained staff, who can treat only a few patients at a time. It is lengthy and not without danger. Patients who should have treatment at the earliest possible moment are therefore compelled to wait for an indefinite period. If, on the other hand, the favourable first impressions with regard to electronarcosis are confirmed, great benefits may accrue in the treatment of schizophrenia, because it will become available to many patients in each hospital.

Moreover, since a method has been devised for passing a constant current through the human brain, a current which in varying intensity can produce controlled narcosis, hyperkinesis, convulsions, and sometimes catalepsy, the possibilities of further research into the electrophysiology of the nervous system are immense. It is likely that, as more knowledge is accumulated, the field for therapy in different psychiatric disorders will be greatly expanded.

hough it is as yet too early to assess the results of tment, the results are distinctly promising.

wing to the simplicity and relative safety of electro- osis, it may possibly take the place of insulin-coma he treatment of choice for early schizophrenia.

e wish to thank Dr. Thomas Beaton for allowing us to t patients at St. James' Hospital, Portsmouth; and E. Jean Straker, of Photo-Union, 12, Soho Square, W.1, he photograph.

DETERMINATION OF HÆMOGLOBIN

I. DETERMINATION BY A CYAN-HÆMATIN METHOD

E J. KING — A., Ph.D. Toronto, D.Sc. Lond.

MARGARET GILCHRIST — M.Sc. Manitoba

of the British Postgraduate Medical School, London

th an Addendum on the selection of suitable green filters by DONALDSON *and* R. B. SISSON, *of the National Physical Laboratory*

METHODS of hæmoglobin determination differ greatly their accuracy. The acid-hæmatin procedures are ually held to be the least reliable, and the cyan- ethæmoglobin procedures to yield the most exact ures. King et al. (1944a) found that several colorimetric ethods would all give good results, provided they ere submitted to precise colorimetry—e.g., Duboscq photo-electric—but that the cyan-methæmoglobin rivative could be measured with greatest accuracy.

The alkaline-hæmatin procedure has the advantage at a standard is easily prepared from crystalline emin (Clegg and King 1942); but it is not as accurate the cyan-methæmoglobin method, and the hæmin andard suffers from the theoretical disadvantage of t giving, mol. (4) for mol., the same colour as hæmo- obin does. Hæmoglobin contains 4 molecules of hæmin, it hæmin yields 30% less colour than it should in mparison with hæmoglobin.

A new method has now been discovered which is even ore accurate than the cyan-methæmoglobin method d uses a hæmatin standard in which the hæmin is used the theoretical proportion of 4 mols. of hæmin to 1 mol. hæmoglobin. The cyan-hæmatin colours produced by emin, on the one hand, and by blood, on the other, o in fact show a slight difference in their spectral bsorption curves (see figure). Both have maxima at 544–48 mμ and minima at 504–510 mμ, but the whole curve r the cyan-hæmatin from blood seems to be slightly isplaced toward the shorter wave-lengths, and its aximum is not quite so pronounced as that for the yan-hæmatin from hæmin. Nevertheless, for some lters which transmit a broad band in the green part of he spectrum, the overall absorptions for cyan-hæmatin rom both sources agree very closely. Thus, with a uitable filter, an amount of hæmin containing 1 mg. of ron will give the same absorption when converted into yan-hæmatin as will the equivalent amount of hæmo- lobin—i.e., that amount which contains 1 mg. of iron. The cyan-hæmatins from both sources are therefore omparable, and consequently hæmin may properly be sed as a natural standard with a suitable filter. Alterna- ively, the colours may be compared in visual instruments without light filters, since they appear identical to the eye, and since the overall absorptions for the whole visible spectrum are not appreciably different.

MATERIALS AND SOLUTIONS

Bloods.—The specimens used have all been from normal healthy human beings or from animals. The human bloods were taken by venepuncture and were oxalated. Those from animals were obtained from the slaughter-house and were defibrinated.

Hæmins.—These were all prepared by the classical procedure of running blood into a hot mixture of glacial acetic acid and potassium-chloride solution. The crystals which separated on cooling were well washed with salt solution and water by decantation and settling, and then by alcohol and ether on a Buchner filter (Delory 1943). The product was usually beautifully crystalline. Amorphous precipitates were occasionally obtained, and these were discarded, since their colours were not to be relied on in either the alkaline hæmatin or the cyan-hæmatin methods—i.e., their extinctions, relative to their iron analyses, were variable, and differed from those of the crystalline products (cf. Gibson and Harrison 1945). No hæmin which is not crystalline should be used as a standard in any hæmoglobin method.

Recrystallisation of hæmin was tried, but without much success. The Fischer (1941) method of solution in chloroform and pyridine and precipitation in hot acetic acid sometimes improved the purity of the specimen but was as apt as not to yield a less pure powder. Recrystallisation was therefore abandoned and the "crude" product always used. These "crude" hæmins were always of a high degree of purity however; and it seems, from a very considerable experience with hæmin preparations, that any crystalline specimen which has been accurately analysed for iron is acceptable as a standard, and that its colour is always directly proportional to its content of iron.

N/10 Hydrochloric Acid.—10 ml. of concentrated HCl diluted to 1 litre.

2% Sodium Cyanide.—20 g. of NaCN (A.R.) dissolved in water and diluted to 1 litre.

5% Sodium Cyanide.—50 g. of NaCN (A.R.) dissolved in water and diluted to 1 litre.

ANALYTICAL PROCEDURES

Iron.—Duplicate samples of 5 ml. of blood, with a little conc. HNO_3, were carefully evaporated to dryness in 50-ml. 'Pyrex' beakers, dried at 110°C, and ashed at 450°C overnight. The ash was dissolved in HCl and titrated with $TiCl_3$. The technique is described in full by Delory (1943), the only modification used being that the $TiCl_3$ was diluted with freshly distilled water, which had been boiled and cooled in a stream of CO_2.

Oxygen.—The Van Slyke manometric method was used as described by Peters and Van Slyke (1932).

A full discussion of the analytical procedures most useful for establishing "base-line" values for the standardisation of hæmoglobin procedures is given by King et al. (1947).

CYAN-HÆMATIN METHOD

Standard Solution of Cyan-hæmatin in 1% Sodium Cyanide.—28·8 mg. of pure crystalline hæmin (8·57% Fe) is weighed into a one-litre volumetric flask; 200 ml. of 5% sodium cyanide is added and water till the flask is nearly full. The mixture is left at room temperature, and occasionally shaken, till all the hæmin is dissolved. It is then made up to the mark and mixed.

Impure hæmins—i.e., those having less than the theoretical content of iron—may be used for the standard, provided they are crystalline and their percentage of iron is known, the assumption being that the impurity present does not contain iron and is non-chromogenic. That this assumption appears to be justified is seen in the results. A hæmin which, for instance, contains 8·41% of iron (instead of the theoretical 8·57%) would be used in the proportion of $\frac{28\cdot 8 \times 8\cdot 57}{8\cdot 41}$ = 29·3 mg./l. of 1% sodium cyanide.

side by means of two adjustable metal clips made of nickel-silver. The two electrodes are about 2 in. square, with rounded edges and rounded corners. The terminals have non-detachable heads and slotted holes and are self-locking. They are made of nickel-plated copper and are non-corrosive. They are easily slipped off the band for cleaning. Saline pads are applied to the electrodes, which are placed over the temples. The patients find the band quite comfortable. As in electric convulsion therapy, care should be taken that none of the contact jelly is continuous between the two electrodes, as this will lessen the current passing through the skull.

Treatment

The apparatus is connected to the mains by plugging in the cable (see figure). Wires run from the terminals on the machine to electrodes applied to the patient's temples. After the "patient circuit" has been completed, the mains switch is turned on. This enables the operator to adjust the ammeter to a predetermined value, generally 160 mA. The treatment is actually started by switching on the patient switch, causing an immediate tonic flexion of the extremities. After about 10 sec. there is a momentary atonia, followed by extension of the legs and opisthotonus. The pulse disappears for a few seconds, after which the heart beats slowly and irregularly. Respiration is arrested, and the patient may become cyanosed.

After 30 sec. the second stage of treatment is begun. The current is reduced to 65 mA. A few clonic twitches occur, lasting a few seconds. Within 15 sec. the patient gasps and thereafter breathes regularly. If the onset of respiration is delayed, or if it is difficult, the rubber tubing may be inserted into the nose. Carbon dioxide and oxygen are administered as soon as the current is reduced. It is usual to increase the current by about 5 mA every 15 sec.

There is a convenient physiological sign which indicates that the correct level of narcosis has been attained. This is a mild inspiratory stridor, which appears in most cases. It is thought to be caused by a moderate apposition of the vocal cords. If the narcosis is too deep, the vocal cords may become too much approximated, and respiration becomes difficult. If the stridor disappears, the patient is probably beginning to come out of the narcosis. In either case the correct level can be attained by raising or lowering the current. In the second stage a current of 140 mA should not be exceeded, as a second onset of severe tonic spasm may ensue.

As a rule the patient remains quiet, and there is considerable flexor tone in the arms, with extensor tone in the legs. Often the hand resembles that in tetany, with the thumb clenched between the second and third digits. The tendon-reflexes disappear at first but reappear in the later stages. The plantar reflex is extensor during the treatment. All these signs, however, are variable.

After 7 min. the current is switched off, and the patient recovers as in electric convulsion therapy, generally within half an hour. Anti-headache tablets should be available in case of need. Under ideal conditions there will be two doctors and at least two nurses. One doctor will manipulate the current. Experience is required to gauge the best current in each case, as there are considerable variations in muscular response. The other doctor will administer the carbon dioxide and oxygen, and two nurses will be able to cope with the patient if he should become unduly restless during or after treatment.

Plan of Treatment

The treatment is given three times a week for four weeks, followed by a week's rest. Thereafter a second course can be given, if a satisfactory result has not yet been attained.

COMPARISON WITH ELECTRIC CONVULSION THERAPY

Electronarcosis is more scientific, because a current of known intensity is passed through the patient. In electric convulsion therapy, on the other hand, the actual current passed through the patient is not known, as the patient's resistance drops during the passage of the current, and these changes are not compensated for as in electronarcosis.

In electronarcosis the current is not so strong as in convulsion therapy and usually does not cause a convulsion at 160 mA, even given for several seconds. When the strong current is reduced, the clonic movements are relatively feeble and last only a few seconds.

In electric convulsion therapy the hypotonic period between initial flexion and extensor rigidity may last up to 1/2 min., but it is only momentary in electronarcosis.

In electric convulsion therapy the extensor rigidity continues for some time after the current has been switched off, but in electronarcosis it ceases when the high current is decreased at the end of 1/2 min. In most cases respiration starts again about 1/2 min. after the current has been switched on, for in electronarcosis the duration of the strong current is the same as that of the fit in electric convulsion therapy—i.e., 1/2 min.

RESULTS OF TREATMENT

Twenty patients have been treated by us. These were all schizophrenics who were definitely hallucinated. They had been ill for various periods and it is as yet too early to assess the results of treatment.

American pioneers in this method of treating schizophrenia have reported results as good as those obtained by insulin-coma therapy (Tietz et al. 1946). Though we were not particularly hopeful when starting this treatment, the results so far attained are distinctly promising. In every case the hallucinations have disappeared, for some weeks at least, and in some instances the recoveries have been most striking after only a month's treatment.

DISCUSSION

Until recently insulin-coma therapy has proved the most successful treatment of early schizophrenia. It has, however, certain disadvantages. Owing to shortage of staff, only a limited number of hospitals can use it. It requires a team of specially trained staff, who can treat only a few patients at a time. It is lengthy and not without danger. Patients who should have treatment at the earliest possible moment are therefore compelled to wait for an indefinite period. If, on the other hand, the favourable first impressions with regard to electronarcosis are confirmed, great benefits may accrue in the treatment of schizophrenia, because it will become available to many patients in each hospital.

Moreover, since a method has been devised for passing a constant current through the human brain, a current which in varying intensity can produce controlled narcosis, hyperkinesis, convulsions, and sometimes catalepsy, the possibilities of further research into the electrophysiology of the nervous system are immense. It is likely that, as more knowledge is accumulated, the field for therapy in different psychiatric disorders will be greatly expanded.

SUMMARY

The physiological state known as electronarcosis is described in dogs and in man.

It has been claimed in America that the procedure is as successful as insulin-coma therapy in treating schizophrenia.

A new portable machine is described, in which a constant current is obtained without the use of thermionic valves.

We have treated 20 schizophrenics, in most cases with 12 treatments in one month.

hough it is as yet too early to assess the results of tment, the results are distinctly promising.

wing to the simplicity and relative safety of electro-cosis, it may possibly take the place of insulin-coma he treatment of choice for early schizophrenia.

e wish to thank Dr. Thomas Beaton for allowing us to t patients at St. James' Hospital, Portsmouth; and E. Jean Straker, of Photo-Union, 12, Soho Square, W.1, the photograph.

DETERMINATION OF HÆMOGLOBIN

I. DETERMINATION BY A CYAN-HÆMATIN METHOD

of the British Postgraduate Medical School, London

ith an Addendum on the selection of suitable green filters by Donaldson *and* R. B. Sisson, *of the National Physical Laboratory*

Methods of hæmoglobin determination differ greatly their accuracy. The acid-hæmatin procedures are ually held to be the least reliable, and the cyan-ethæmoglobin procedures to yield the most exact gures. King et al. (1944a) found that several colorimetric ethods would all give good results, provided they ere submitted to precise colorimetry—e.g., Duboscq photo-electric—but that the cyan-methæmoglobin erivative could be measured with greatest accuracy.

The alkaline-hæmatin procedure has the advantage at a standard is easily prepared from crystalline æmin (Clegg and King 1942); but it is not as accurate s the cyan-methæmoglobin method, and the hæmin andard suffers from the theoretical disadvantage of ot giving, mol. (4) for mol., the same colour as hæmo-lobin does. Hæmoglobin contains 4 molecules of hæmin, ut hæmin yields 30% less colour than it should in omparison with hæmoglobin.

A new method has now been discovered which is even ore accurate than the cyan-methæmoglobin method nd uses a hæmatin standard in which the hæmin is used the theoretical proportion of 4 mols. of hæmin to 1 mol. f hæmoglobin. The cyan-hæmatin colours produced by æmin, on the one hand, and by blood, on the other, o in fact show a slight difference in their spectral bsorption curves (see figure). Both have maxima at 544–48 mμ and minima at 504–510 mμ, but the whole curve or the cyan-hæmatin from blood seems to be slightly isplaced toward the shorter wave-lengths, and its aximum is not quite so pronounced as that for the yan-hæmatin from hæmin. Nevertheless, for some lters which transmit a broad band in the green part of he spectrum, the overall absorptions for cyan-hæmatin rom both sources agree very closely. Thus, with a uitable filter, an amount of hæmin containing 1 mg. of ron will give the same absorption when converted into yan-hæmatin as will the equivalent amount of hæmoglobin—i.e., that amount which contains 1 mg. of iron. The cyan-hæmatins from both sources are therefore comparable, and consequently hæmin may properly be used as a natural standard with a suitable filter. Alternatively, the colours may be compared in visual instruments without light filters, since they appear identical to the eye, and since the overall absorptions for the whole visible spectrum are not appreciably different.

MATERIALS AND SOLUTIONS

Bloods.—The specimens used have all been from normal healthy human beings or from animals. The human bloods were taken by venepuncture and were oxalated. Those from animals were obtained from the slaughter-house and were defibrinated.

Hæmins.—These were all prepared by the classical procedure of running blood into a hot mixture of glacial acetic acid and potassium-chloride solution. The crystals which separated on cooling were well washed with salt solution and water by decantation and settling, and then by alcohol and ether on a Buchner filter (Delory 1943). The product was usually beautifully crystalline. Amorphous precipitates were occasionally obtained, and these were discarded, since their colours were not to be relied on in either the alkaline hæmatin or the cyan-hæmatin methods—i.e., their extinctions, relative to their iron analyses, were variable, and differed from those of the crystalline products (cf. Gibson and Harrison 1945). No hæmin which is not crystalline should be used as a standard in any hæmoglobin method.

Recrystallisation of hæmin was tried, but without much success. The Fischer (1941) method of solution in chloroform and pyridine and precipitation in hot acetic acid sometimes improved the purity of the specimen but was as apt as not to yield a less pure powder. Recrystallisation was therefore abandoned and the "crude" product always used. These "crude" hæmins were always of a high degree of purity however; and it seems, from a very considerable experience with hæmin preparations, that any crystalline specimen which has been accurately analysed for iron is acceptable as a standard, and that its colour is always directly proportional to its content of iron.

N/10 Hydrochloric Acid.—10 ml. of concentrated HCl diluted to 1 litre.

2% Sodium Cyanide.—20 g. of NaCN (A.R.) dissolved in water and diluted to 1 litre.

5% Sodium Cyanide.—50 g. of NaCN (A.R.) dissolved in water and diluted to 1 litre.

ANALYTICAL PROCEDURES

Iron.—Duplicate samples of 5 ml. of blood, with a little conc. HNO_3, were carefully evaporated to dryness in 50-ml. 'Pyrex' beakers, dried at 110°C, and ashed at 450°C overnight. The ash was dissolved in HCl and titrated with $TiCl_3$. The technique is described in full by Delory (1943), the only modification used being that the $TiCl_3$ was diluted with freshly distilled water, which had been boiled and cooled in a stream of CO_2.

Oxygen.—The Van Slyke manometric method was used as described by Peters and Van Slyke (1932).

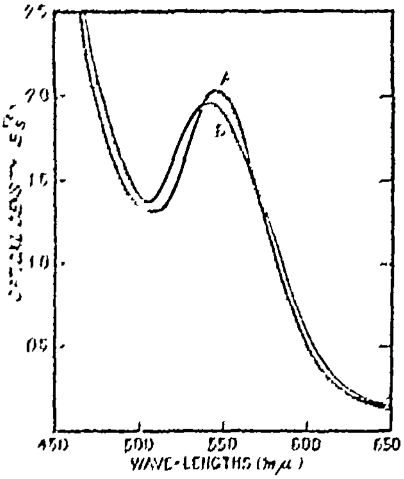
A full discussion of the analytical procedures most useful for establishing "base-line" values for the standardisation of hæmoglobin procedures is given by King et al. (1947).

CYAN-HÆMATIN METHOD

Standard Solution of Cyan-hæmatin in 1% Sodium Cyanide.—28·8 mg. of pure crystalline hæmin (8·57% Fe) is weighed into a one-litre volumetric flask; 200 ml. of 5% sodium cyanide is added and water till the flask is nearly full. The mixture is left at room temperature, and occasionally shaken, till all the hæmin is dissolved. It is then made up to the mark and mixed.

Impure hæmins—i.e., those having less than the theoretical content of iron—may be used for the standard, provided they are crystalline and their percentage of iron is known, the assumption being that the impurity present does not contain iron and is non-chromogenic. That this assumption appears to be justified is seen in the results. A hæmin which, for instance, contains 8·41% of iron (instead of the theoretical 8·57%) would be used in the proportion of $\frac{28\cdot8\times8\cdot57}{8\cdot41}=29\cdot3$ mg./l. of 1% sodium cyanide.

Macro-method for Blood.—0·5 ml. of blood is accurately measured into a 100-ml. volumetric flask containing about 75 ml. of 0·1 *N* hydrochloric acid, with which it is well mixed. About 10 min. is allowed for the transformation of hæmoglobin into acid hæmatin, as shown by the solution turning a clear yellow with no trace of residual pink; 20 ml. of 5% sodium cyanide is added and water to the mark. The solution is mixed, and the intensity of the bright red colour of the cyan-hæmatin is measured by comparison with the standard solution.



Optical density of cyan-hæmatin solutions from hæmin (A) and from hæmoglobin (B), 1 cm. layer of solution containing 1 mg. hæmin or hæmoglobin iron per 100 ml.

Micro-method for Blood.—0·05 ml. of blood is mixed with 4·95 ml. of 0·1 *N* hydrochloric acid and left for 10 min. to complete the transformation to acid hæmatin; 5 ml. of 2% sodium cyanide is then added and the solution mixed. (Alternatively, 0·02 ml. blood, with 1·98 ml. 0·1 *N* hydrochloric acid, and 2 ml. 2% sodium cyanide may be used.) The sodium cyanide may conveniently be added from an automatic pipette obtainable from any scientific or medical supply house.

These three methods give the same final dilution of 1 in 200.

Measurement of Colour Intensity.—Any colorimeter or photometer (visual or photo-electric) may be used for measuring the colour of cyan-hæmatin. A light filter, with maximum transmission between 530 and 550 mμ, transmitting a fairly broad band in the green part of the spectrum (limits about 480–600 mμ), such as Chance green or Ilford T.C. green, is suitable. For standardisation of high accuracy the green filters, especially those with narrow transmission bands, have to be selected very carefully for reasons which are dealt with below.

All reported measurements were made in a King (1942) photo-electric colorimeter. This is a single photo-cell instrument, and is fitted with square glass cells (1 cm. optical thickness) and a Chance OGR1 green light filter. The zero settings were made with water in the cell; the readings were taken on the linear scale, and the extinctions calculated from E = log (Io/I).

TABLE I—SPECIFIC EXTINCTION COEFFICIENTS OF CYAN-HÆMATIN SOLUTIONS OF VARIOUS PREPARATIONS OF HÆMIN

(Solutions of crystalline hæmin (about 30 mg.) in 1 litre of 1% sodium cyanide, King photo-electric colorimeter, 1 cm. cell, Chance OGR1 green filter.)

Code	Fe (%)	E_S^{Fe} (for 1 mg. Fe/100 ml.)
(16 BDH)	8·41	1·64
(17 GED)	8·26	1·58
(18 KJK)	8·26	1·56
(19 BDH)	8·13	1·58
(23 MG)	8·26	1·64
(D & G)	7·60	1·59
(26 MG)	8·36	1·55
(28 AH)	8·00	1·60
(29 BDH)	8·12	1·63
(30 AH)	8·42	1·57

Mean = 1·59
Standard deviation = 0·03
Coefficient of variation = 2·05%

Calculation of Results.—The standard cyan-hæmatin solution is equivalent to 14·8 g. of hæmoglobin per 100 ml. of blood at a 1 in 200 dilution. This concentration has been chosen because it is that of the B.S.I. Haldane standard (Macfarlane and O'Brien 1944, King et al. 1944). 28·8 mg. of hæmin is therefore the equivalent of 14,80- 200=740 mg. of hæmoglobin. Since hæmin co 8·57% iron and hæmoglobin 0·334%, the 28·8 mg. hæmin and the 740 mg. of hæmoglobin both co 2·46 mg. iron. From this it will be apparent how hæmoglobin and hæmin are equatable on an iron basis.

With a photo-electric colorimeter the concentration of hæmoglobin in any blood, determined in the above manner, is calculated as follows:

$$\frac{\text{Extinction of test}}{\text{Extinction of standard}} \times 14{\cdot}8 = \text{g. of hæmoglobin/100 ml.,}$$

or

$$\frac{\text{Extinction of test}}{\text{Extinction of standard}} \times 100 = \%\ \text{of Haldane (B.S.I.) normal}$$

For some purposes, such as the comparison of colour intensities of different standard solutions, it may useful to express results as extinction coefficients to some constituent of the hæmins which can be determined with a high degree of accuracy. As has suggested, iron is the constituent which best the degree of purity of the specimen and can be most accurately determined. Extinctions of standard so are divided by their iron contents to give the "extin per mg. of iron.": this is known as the "specific extinction coefficient relative to iron," for which the symbol E_S^{Fe} is used.

TABLE II—AGREEMENT OF CYAN-HÆMATIN STANDARDS VARIOUS HÆMINS

(Extinction coefficients for solutions of crystalline hæmins (about 32 mg.) in 1% KCN (1 litre), King photo-electric colorimeter, 1 cm. cell, Chance OGR1 green filter.)

Hæmin no.	Fe (%)	E_S^{Fe}
(16 BDH)	8·41	1·58
(17 GED)	8·26	1·64
(19 BDH)	8·13	1·66
(26 MG)	8·36	1·62
(28 AH)	8·00	1·63
(30 AH)	8·24	1·57
(31 horse)	6·67	1·62
(33 BDH)	8·30	1·63
(34 BDH)	8·32	1·58
(35 BDH)	8·41	1·59

Average = 1·61
Coefficient of variation = 1·87

The "extinction coefficient" is equally useful for expressing the results for hæmoglobin; and, since the cyan-hæmatins from hæmin and from hæmoglobin are equatable on an iron basis, the E_S^{Fe} for hæmin and for hæmoglobin should be equal.

RESULTS

Similarity of Colour of Cyan-hæmatins from Hæmin and from Blood

The cyan-hæmatin solutions, prepared as described above from several specimens of hæmin and from several bloods, were indistinguishable to the unaided eye. Their colour was of a bright burgundy quality, closely similar to that of the cyan-methæmoglobin. When read in a visual photometer with spectrum light filters, no dissimilarity was detected between the coloured solutions from hæmins and from bloods. With the Spekker absorptiometer and eight light filters covering the visible sp the absorptions of the two cyan-hæmatins were the within the limits of error of the instrument. De spectral absorption curves (see figure) were carried on a photo-electric spectrophotometer at the N

ysical Laboratory by Mr. R. Donaldson and Mr. R. B. son. They demonstrate the substantial similarity of e spectral characteristics of the cyan-hæmatins from min and from hæmoglobin. The lack of identity erred to in the introduction is, however, obvious. e cyan-hæmatin from blood has a less pronounced ak, and the whole curve appears to be slightly shifted the left. Whether this slight difference is due simply the presence of extraneous matter in the solutions ade from blood, as compared with the simpler solutions om crystalline hæmin, or is derived from some chemical ssimilarity between cyan-hæmatins prepared from the o different sources, is not yet clear. It is not a pH fect.

onstancy of Colour Production from Various Hæmins

In March, 1945, standard solutions were made from n different hæmins prepared by several persons, some them from a commercial source. These hæmins had l been analysed for iron by ourselves by the titanous-loride method; some of the analyses were checked the bichromate procedure, and others by a gravimetric ethod. The specimens (about 30 mg. each) were refully weighed and left to dissolve for two days before ing made to volume and read in the photo-electric lorimeter. The readings were all of an order to correond with extinctions of about 0·4—i.e., they were in e range of maximum accuracy of the instrument. ach determined extinction was factored by the content hæmin iron of the solution (from the iron percentage y analysis and the weight taken), and the resultant gure recorded. These extinction coefficients would of urse all be identical if all the hæmins were completely ure, and if all analytical procedures were free from ror. That the results approximate to this ideal is seen table I, where a coefficient of variation of only 2% as found for hæmins which differed in iron content as idely as 7·5% and 8·42% Fe. Since each result includes e cumulative errors due to the iron analysis, impurities the hæmin, and inaccuracies in measurement—ravimetric, volumetric, and colorimetric—it is remarkble that the figures agree so well. Those listed below re even better.

A second set of the standards was prepared in January, 946. Several of the specimens were the same as those sed in the first set; others were new. The results are ontained in table II, and the agreement is almost as ood as that usually obtained with multiple photometric neasurements of coloured solutions prepared from a ingle specimen

Permanence of Cyan-hæmatin Standards

The two sets of standard solutions (tables I and II) have been preserved at room temperature in diffuse daylight on a shelf of the laboratory. Their intensities of colour have been redetermined at intervals, and it is apparent that the cyan-hæmatin colour deteriorates slowly. During eighteen months the average extinction coefficient of the first ten standards fell from $E_S^{Fe}=1·59$ in March, 1945, to $E_S^{Fe}=1·47$ in November, 1946. The second set, which averaged $E_S^{Fe}=1·61$ in March, 1946, read 1·59 in June (coeff. of variation, 1·69) and 1·53 in November. It appears from this that a standard solution may be used for as long as eighteen months without introducing any serious error, provided the value of E is reduced by about $^1/_2$% per month. For work of the highest accuracy, fresh standard solutions should be prepared every three months.

Cyan-hæmatins from Blood

Three separate experiments have been carried out: one with a mixed lot of human and animal bloods; one with specimens from normal adult males; and one from normal adult females. The results are set out as extinction coefficients for the two experiments with adult male and female bloods; and as a comparison of hæmoglobin figures (g./100 ml. of blood), derived from the colorimetric method and from the titanous-chloride method, for the human and animal bloods. It should be noted that these two ways of expressing results come to one and the same thing: a titanous-chloride analysis for iron, an oxygen capacity, and a colorimetric cyan-hæmatin determination were carried out on each blood; and the determined values could be expressed either as extinction coefficients or as grammes of hæmoglobin by each method. The extinction coefficients given in table III show the closeness of the values obtained for blood with those for the hæmins in tables I and II, and the slight difference in the values for E_S^{Fe} calculated directly from the iron analyses and indirectly from the oxygen capacities (1 atom of iron taken to be the equivalent of 1 molecule of oxygen). The hæmoglobin figures in table IV demonstrate the excellent agreement between the figures obtained by the colorimetric method and those given by the "base-line" determinations with the titanous chloride.

DISCUSSION

We believe this to be the most satisfactory hæmoglobin method we have so far used. It is easy and reasonably quick. The troublesome features of the Haldane carboxyhæmoglobin method, the alkaline hæmatin method, and

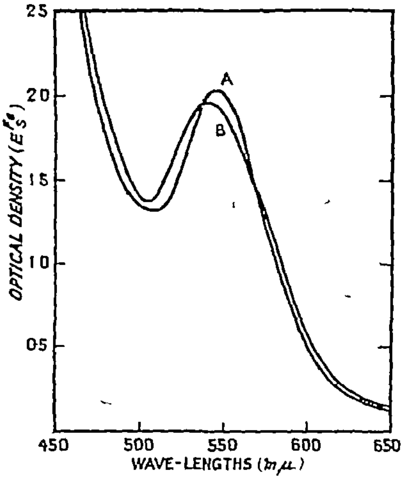
* Colours compared against a standard made from crystalline hæmin. Results calculated on the basis of 1 hæmin-Fe = 1 hæmoglobin-Fe.

Macro-method for Blood.—0·5 ml. of blood is accurately measured into a 100-ml. volumetric flask containing about 75 ml. of 0·1 *N* hydrochloric acid, with which it is well mixed. About 10 min. is allowed for the transformation of hæmoglobin into acid hæmatin, as shown by the solution turning a clear yellow with no trace of residual pink; 20 ml. of 5% sodium cyanide is added and water to the mark. The solution is mixed, and the intensity of the bright red colour of the cyan-hæmatin is measured by comparison with the standard solution.



Optical density of cyan-hæmatin solutions from hæmin (A) and from hæmoglobin (B), 1 cm. layer of solution containing 1 mg. hæmin or hæmoglobin iron per 100 ml.

Micro-method for Blood.—0·05 ml. of blood is mixed with 4·95 ml. of 0·1 *N* hydrochloric acid and left for 10 min. to complete the transformation to acid hæmatin; 5 ml. of 2% sodium cyanide is then added and the solution mixed. (Alternatively, 0·02 ml. blood, with 1·98 ml. 0·1 *N* hydrochloric acid, and 2 ml. 2% sodium cyanide may be used.) The sodium cyanide may conveniently be added from an automatic pipette obtainable from any scientific or medical supply house.

These three methods give the same final dilution of 1 in 200.

Measurement of Colour Intensity.—Any colorimeter or photometer (visual or photo-electric) may be used for measuring the colour of cyan-hæmatin. A light filter, with maximum transmission between 530 and 550 mμ, transmitting a fairly broad band in the green part of the spectrum (limits about 480–600 mμ), such as Chance green or Ilford T.C. green, is suitable. For standardisation of high accuracy the green filters, especially those with narrow transmission bands, have to be selected very carefully for reasons which are dealt with below.

All reported measurements were made in a King (1942) photo-electric colorimeter. This is a single photo-cell instrument, and is fitted with square glass cells (1 cm. optical thickness) and a Chance OGR1 green light filter. The zero settings were made with water in the cell; the readings were taken on the linear scale, and the extinctions calculated from $E = \log (Io/I)$.

TABLE I—SPECIFIC EXTINCTION COEFFICIENTS OF CYAN-HÆMATIN SOLUTIONS OF VARIOUS PREPARATIONS OF HÆMIN

(Solutions of crystalline hæmin (about 30 mg.) in 1 litre of 1% sodium cyanide, King photo-electric colorimeter, 1 cm. cell, Chance OGR1 green filter.)

(D & G)	7·60	1·59
(26 MG)	8 36	1·55
(28 AH)	8·00	1·60
(29 BDH)	8 12	1 63
(30 AH)	8·42	1·57

Mean = 1 59
Standard deviation = 0 03
Coefficient of variation = 2 05%

Calculation of Results.—The standard cyan-hæmatin solution is equivalent to 14·8 g. of hæmoglobin 100 ml. of blood at a 1 in 200 dilution. This concen has been chosen because it is that of the B.S.I. H standard (Macfarlane and O'Brien 1944, King et al. 1 28·8 mg. of hæmin is therefore the equivalent of 14·8 × 200 = 740 mg. of hæmoglobin. Since hæmin con 8·57% iron and hæmoglobin 0·334%, the 28·8 mg hæmin and the 740 mg. of hæmoglobin both con 2·46 mg. iron. From this it will be apparent how hæmoglobin and hæmin are equatable on an iron basis.

With a photo-electric colorimeter the concen of hæmoglobin in any blood, determined in the a manner, is calculated as follows:

$$\frac{\text{Extinction of test}}{\text{Extinction of standard}} \times 14{\cdot}8 = \text{g. of hæmoglobin/100 ml.,}$$

or

$$\frac{\text{Extinction of test}}{\text{Extinction of standard}} \times 100 = \text{\% of Haldane (B.S.I.) normal}$$

For some purposes, such as the comparison of colour intensities of different standard solutions, it may be useful to express results as extinction coefficients relative to some constituent of the hæmins which can be determined with a high degree of accuracy. As has been suggested, iron is the constituent which best indicates the degree of purity of the specimen and can be most accurately determined. Extinctions of standard solutions are divided by their iron contents to give the "extinction per mg. of iron": this is known as the "specific extinction coefficient relative to iron," for which the symbol E^{Fe}_S is used.

TABLE II—AGREEMENT OF CYAN-HÆMATIN STANDARDS FROM VARIOUS HÆMINS

(Extinction coefficients for solutions of crystalline hæmins (about 32 mg.) in 1% KCN (1 litre), King photo-electric colorimeter, 1 cm. cell, Chance OGR1 green filter.)

Hæmin no.	Fe (%)	E^{Fe}_S
(16 BDH)	8·41	1 58
(17 GED)	8 26	1 64
(19 BDH)	8 13	1 66
(26 MG)	8·36	1·62
(28 AH)	8 00	1 63
(30 AH)	8 24	1 57
(31 horse)	6 67	1·62
(33 BDH)	8·30	1 63
(34 BDH)	8 32	1·55
(35 BDH)	8 41	1·59

Average = 1 61
Coefficient of variation = 1·87

The "extinction coefficient" is equally useful for expressing the results for hæmoglobin; and, since the cyan-hæmatins from hæmin and from hæmoglobin are equatable on an iron basis, the E^{Fe}_S for hæmin and for hæmoglobin should be equal.

RESULTS

Similarity of Colour of Cyan-hæmatins from Hæmin and from Blood

The cyan-hæmatin solutions, prepared as described above from several specimens of hæmin and from several bloods, were indistinguishable to the unaided eye. Their colour was of a bright burgundy quality, closely similar to that of the cyan-methæmoglobin. When read in a visual photometer with spectrum light filters, no dissimilarity was detected between the coloured solutions from hæmins and from bloods. With the Spekker absorptiometer and eight light filters covering the visible spectrum, the absorptions of the two cyan-hæmatins were the same within the limits of error of the instrument. Detailed spectral absorption curves (see figure) were carried out on a photo-electric spectrophotometer at the National

MEPACRINE ERUPTIONS

A CASE IN THE BRITISH ISLES

BRIAN RUSSELL
M.D. Lond., M.R.C.P., D.P.H.
SISTANT PHYSICIAN, SKIN DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL

IN view of the descriptions from both sides of the tlantic (see *Lancet* 1945) of a dermatosis arising, after e taking of mepacrine, in the Mediterranean and South-est Pacific areas, remarkable for its protean character, nd called "eczematous and pigmentary lichenoid ermatitis," "atypical lichen planus," and "tropical chenoid dermatitis," the report of a case arising in the ritish Isles is of interest.

Nisbet (1945) describes the condition as superficially esembling almost every known dermatosis but with the llowing characteristics: pigmented flat or hypertrophic chenoid lesions, persistent circumscribed erythemata, volvement of external ears and around eyes, extreme hronicity, decided tendency to secondary infection, eneralised exudative eczematisation or exfoliation, and eculiar pigmentary changes.

The three rough categories of patchy eczematoid, ypertrophic lichenoid, and general exfoliative types ay all arise in any one case at different phases.

The initial lesions appear anywhere, but especially on he backs of hands and feet, on the ears, or, in seborrhœic ubjects, in seborrhœic sites. Mucosæ and external enitalia are often affected; but, though the mucosal esions may be identical with those of lichen planus, he elementary papules of this disease are never present n the skin. Patients were in hospital for an average f about three months after evacuation from the tropics.

Schmitt et al. (1945), reporting 47 cases, noted mucosal involvement in about a third, and described the sequelæ as pigmentary dystrophy, cutaneous atrophy (reticulated or confluent), patchy alopecia, nail involvement, and sweat and sebaceous glandular inactivation. The incidence is regarded as extremely small among 'Quinacrine' takers. Sulzberger (1945) estimates the incidence as 2 per 1000 at most in areas where 'Atebrin' administration as a suppressive was most faithfully carried out, a surprisingly low incidence when the selective concentration of the drug in the skin and liver is taken into consideration.

The interval between starting to take the drug and the onset is 1–11 months, with an average of $3^1/_2$ months, with no apparent relationship to the degree of severity. The occurrence seems to depend on dosage, suggesting saturation and toxicity rather than idiosyncrasy. Improvement occurs 2–8 weeks after withdrawal. Relapse does not occur after one dose but only after 2 or more days' therapy, suggesting cumulative action. Cases were observed which had lasted 9–11 months.

The initial eruption is variable in type and may closely resemble fungous infection, heat rash, urticaria, pityriasis rosea, psoriasis, contact dermatitis, or scabies. The secondary eruption may resemble lichen planus, infectious eczematoid dermatitis, prurigo nodularis, mycosis fungoides, lepromatous leprosy, syphilis, lymphoblastoma, or acanthosis nigricans. The buccal lesions closely resemble lichen planus or leukoplakia. Bagby (1945) believes that factors are involved besides dietary deficiency and toxicity from quinacrine hydrochloride.

Peterkin and Hair (1946) point out that the primary lesion may appear on the site of a preceding dermatosis, and they noted a relapse in 5–9 days, following the readministration of mepacrine, in three persons in whom the eruption had almost subsided. They report intense pruritus, oral lesions, and frequent loss of weight and malaise, often followed by intense pigmentation, and the resemblance of the dermatosis to lupus erythematosus, psoriasis, seborrhœic dermatitis, vitamin-B deficiency, phrynoderma, fixed drug eruptions, and some of the conditions described by Schmitt et al. (1945).

Wilson (1946) considers vitamin deficiency (particularly of vitamin A), quinacrine hydrochloride, and allergy as ætiological factors. Bereston and Cheney (1946) found the time of recovery in mild and moderate cases to be shortened by large doses of vitamin-B complex. In more severe cases the earlier recovery was not noted.

CASE-RECORD

A company director, aged 61, had taken quinine for over 25 years as a malarial suppressive. On Jan. 1, 1946, he started taking mepacrine instead, the first course being three tablets of 0·1 g. t.d.s. for one day, two tablets t.d.s. for two days, one tablet t.d.s. for three days, followed by 0·1 g. daily for six weeks. After this he took three further courses at 6–8 week intervals of two tablets t.d.s. for two days, followed by reduction to one tablet daily.

In June, 1946, he began to complain of a "general inflammation" on one calf at a site at which he had previously experienced itching from sitting near the fire or taking a hot bath. The rash spread to both legs and forearms, and to a lesser extent to the trunk, and now developed into intensely itching red patches, soon becoming scaly. The condition was treated as psoriasis, without improvement. The tongue, lips, and buccal mucosa were not involved.

In October the scalp became scurfy, and he noted a purulent discharge from the right ear, which was slightly painful. Shortly afterwards the scalp became matted with discharge.

His general health had remained unimpaired; he had always been thin, but his appetite was unaffected, and his diet had consisted of little meat, milk, fat, or fruit, but many boiled puddings, potatoes, and green vegetables. There was no history of allergy or of skin disorder, and no family history of psoriasis. He had not been abroad for over twelve years.

On examination on Nov. 8 he was very thin, with the skin tinted a deep yellow. Conjunctivæ normal. Pustular the oxyhæmoglobin method—viz., respectively, the necessity of using pure CO or coal-gas, of heating, and of instability of colour—are absent. The necessary reagents are simple and easily obtained, the reactions leading to the colour production are carried out at room temperature, and the colour produced is stable for a long time.

It is perhaps unfortunate that the best methods for hæmoglobin determination depend on the production of cyanide derivatives. But there seems to be no doubt that this is so; and it is therefore useful to inquire if sodium cyanide is in fact as apt to constitute a danger in the hands of laboratory technical assistants as many physicians think it is. We believe that in the absence of any intention of self-poisoning there is no danger at all. The cyan-hæmatin method for hæmoglobin has been in use in this school for two years, and no suspicion of any trouble has occurred. Moreover, cyanide solutions are daily used for uric-acid determinations in biochemical laboratories all over the world. One of us has been associated with such laboratories for years, and has never encountered a case among his own technical staff, or heard of one elsewhere, of an operator wittingly or unwittingly getting cyanide into his mouth. It is well known that technicians often, some habitually, measure sodium-cyanide solution with pipettes, though most laboratories prefer to add it from a burette.

For hæmoglobinometry the NaCN solution was at first added from a burette, but it has been found to be more convenient and quicker to use one of the ordinary automatic self-filling pipettes, mounted on a stand, which are in routine use in most analytical laboratories.

The fact that an easily procurable solid crystalline substance, hæmin, can be used for a standard is a great advantage. The standard solution is simple to prepare and lasts a reasonable time. Cyan-hæmatin has recently been proposed by Drabkin (1945) as a standard solution for the cyan-methæmoglobin procedure, which is widely used in America; and it appears to have been satisfactory for this purpose. It is even more satisfactory for the present method, for which it forms a natural standard, having the advantage that the colours produced in standard and in test are comparable on a stoichiometric basis.

SUMMARY

A cyan-hæmatin procedure is described for the colorimetric determination of hæmoglobin. A solution of crystalline hæmin in cyanide is used as the standard.

The colours produced by hæmin and by hæmoglobin are comparable on a theoretical basis.

Several samples of hæmin and several bloods have given colours which are directly proportional to their iron contents.

The results of hæmoglobin estimations by the cyan-hæmatin method show a high degree of accuracy.

This procedure has been developed during the course of an extensive investigation of hæmoglobin methods undertaken as part of a programme of research carried out here, at Oxford, and at Cardiff, for the subcommittee on analytical methods of the Medical Research Council. The expenses incurred were partly defrayed by a grant from the Medical Research Council, to whom grateful acknowledgment is made. Our thanks are also due to Dr. R. G. Macfarlane, who supplied us with some of the bloods, and to Miss K. Glaser, Mr. W. Weeden, and Mr. A. F. Hoffler for valuable technical assistance.

Selection of Suitable Green Filters

(R. DONALDSON AND R. B. SISSON)

Two main considerations govern the choice of a suitable filter for matching the absorptions of these cyan-hæmatin solutions with slightly dissimilar spectral absorptions: (1) solutions of the same strength—i.e., having equivalent amounts of hæmin and hæmoglobin—shall have the same absorption and shall therefore match when viewed through the filter; and (2) the absorption must be proportional to iron concentration.

The fulfilment of the second requirement is only necessary for instruments where there is a [illegible] scale—e.g., in the usual type of photo-electric colorimeter or in grey wedge photometers. Where the thickness of the solution is varied, as in the Duboscq type of colorimeter, the filter need not meet the second requirement.

The ideal filter satisfying these requirements would transmit only monochromatic light of wave-length 535 mμ, the wave-length at which the two spectral curves intersect. Since all green filters transmit a wave-band of at least 50 mμ, both these requirements cannot be satisfied exactly. It is therefore necessary to select a type of filter which will give the best approximation.

The extended transmission band will not upset the first requirement provided the spectral curve of the filter is of such a shape that the higher transmission of the hæmoglobin cyan-hæmatin to the right of the filter peak is balanced by the higher transmission of the "hæmin" curve to the left of the peak. The extended transmission band also infringes to some extent the second requirement—i.e., the proportionality of the absorption-iron relation. This occurs even though the solutions obey Beer's law very closely. The narrower the transmission band of the filter, the better the proportionality; but there is the disadvantage that many green filters with narrow transmission bands have also a high transmission in the far red region of the spectrum, a characteristic which further upsets the proportionality relation

Results

A number of filters have been examined to see if they are suitable for the measurement of these cyan-hæmatin solutions. If the spectral transmission of the filter is known, the absorptions can be calculated by standard photometric methods. The necessary additional data are the spectral response curves for the average eye and for E.E.L. photo-cells typical of those used on photo-electric colorimeters.

Table v gives the results for solutions viewed through several filters and without a filter. The absorptions of cyan-hæmatin solutions from hæmin (28·8 mg) are expressed as percentages of the absorption of an equivalent amount of hæmoglobin (740 mg.). If the first requirement were exactly satisfied, the entry would be 100.

Table vi shows how these filters meet the second requirement. The spectral absorptions of cyan-hæmatin solutions from hæmoglobin (740 mg. ≡ 100%) of strengths 120%, 100%, and 40% were calculated with Beer's law. For these solutions the errors in proportionality were obtained. If the second requirement were exactly satisfied, the entries in columns 3 and 5 would be 120% and 40%.

TABLE V—ABSORPTIONS OF CYAN-HÆMATIN SOLUTIONS DERIVED FROM HÆMIN (28·8 mg./l.) EXPRESSED AS PERCENTAGES OF ABSORPTION OF AN EQUIVALENT AMOUNT OF HÆMOGLOBIN (740 mg./l.)

Filter	Method of observation	Absorption (%)

Ilford Mercury Green 807	Visual Photo-electric	98·4 98·1
Ilford Spectrum Green 604	Visual Photo-electric	95·6 95·5
No filter	Visual Photo-electric	98·0 96·5

e descending aorta, or an acute hæmorrhagic pancreatitis, considered. The phenomenally low B.P., however, ested an addisonian crisis or the Waterhouse-Friderichsen rome seen in fulminating septicæmic conditions, such as ingococcal bacteræmia.

uring the examination the patient coughed up brown cious blood-streaked sputum, and we tentatively diagnosed inating heliotrope influenza or Friedländer's pneumonia.

ment and Progress

lood for culture was taken and patient was given 1 c.cm. Pituitrin' and 100,000 units of intramuscular penicillin, wed by 100,000 units three hours later, and then 30,000 s three-hourly up to a total dosage of 1·5 mega units. sma drips, glucose-saline, pituitrin, and adrenaline ctions all failed to raise his B.P.

ext morning there was a striking improvement in the ient's appearance. His eyes had lost their cadaveric earance. Tongue moist and nearly clean; pulse-rate 112; temperature 99·4°F and respirations 26. He was tally alert and asked for food. Whatever the causal anism, we believed that penicillin was being effective, ugh his B.P. remained at 60/30. Blood-urea, which on nission was 75 mg. per 100 ml., had risen to 115 mg. the morning of the 25th, and there was anuria.

n the evening, in view of his lack of urinary output and sistently low B.P., 10 c.cm. of 1/1000 adrenaline hydro-oride was given in an hour by intravenous drip in 1 pint of ne. At first the patient became very distressed and breath-; but, when the flow was reduced to 90–100 drops a ute, the coughing ceased and the B.P. rose at once to 150/85. en the drip was reduced to 72–80 drops a minute, his B.P. ained constant at about 120/70 throughout the night, and passed 3 pints of urine.

he drip was reduced to 28 drops a minute during the night see whether his B.P. would remain at a reasonable level. It l at once, however, to 80/45, and a more rapid rate of flow pt the systolic pressure at 120 or above.

At 4 A.M. on the 26th patient had a severe rigor, and the ip was discontinued. Shortly before it was taken down, c.cm. of 1/1000 adrenaline had been injected into the men of the drip tube just above the cannula. There was response in the B.P., which had fallen to 55/20. It was nsidered that the patient had ceased to react to adrenaline.

On the 27th saline-adrenaline drips were continued through-t the day but it was found that on previous dosage the P. would not rise above 75/50. At 5 P.M., therefore, 15 c.cm. adrenaline was added to a pint of glucose-saline. The P. improved within the first ten minutes, and rose to 140/90, ing maintained at 120/60 by regulating the drip. It seemed ear that the adrenaline was losing its action, and later it came necessary to add 20 c.cm. of adrenaline to a pint of line and keep the drip at 60 drops a minute to maintain the stolic pressure at 120. His urinary output was good roughout the day.

Later this dosage of adrenaline failed to maintain his B.P., d 40 c.cm. of adrenaline had to be added to saline and en at 40 drops a minute to keep the systolic pressure at 120. At midnight he had again ceased to react to adrenaline and e B.P. had fallen to 75/55. His pulse-rate rose to 140, d respirations became deep and sighing. Throughout this ther drastic treatment we had feared an acute heart-failure, d drips were now discontinued. We believed the patient as either in extremis or undergoing a crisis. His B.P. fell ring the night to 55/30.

On the 28th there was much improvement in the patient's neral appearance and behaviour. He appeared well, his lse was better, and the pulse-rate fell to between 72 and 80, is temperature was now subnormal, his tongue moist and lean, and his respirations were 20. His urinary output was ll well maintained. During all this period oxygen and O₂ had been given, often continuously. His B.P. started to e very slowly and reached, at its best, 88/64. No further rips were given, and it was hoped patient's adrenal function ould slowly become re-established.

On the 29th his general improvement was maintained, and e was always hungry; and his systolic pressure remained n the region of between 75 and 88.

On the 30th progress was maintained. The systolic pressure eached just over 90 for a short period. He left hospital month after admission, with a B.P. of 130/75.

Up to the time of cessation of saline-adrenaline drips, 85 c.cm. of 1/1000 adrenaline hydrochloride was administered ntravenously over 51 hours in 15 pints of saline to maintain his B.P. and promote urinary output. This dosage works out at an average of 19 c.cm. per pint, or 5·6 c.cm. an hour.

X-ray Findings

Radiography on the morning after his admission showed a dense pneumonia of lobar type in the right upper lobe, and appearances in both lungs suggesting congestive heart-failure. This condition was probably infective rather than congestive.

Further Observations

The physical signs in the chest on the day after admission agreed with the X-ray findings, which showed consolidation of the upper right lobe. Further examination showed a rapid resolution of the pneumonic process.

The pulse during convalescence was at first very slow, beating at a steady 48 per min. Electrocardiography showed no abnormality besides bradycardia. Later it showed a normal rhythm with no impairment in conduction. At this time the pulse-rate was 70 per min., and remained steady afterwards.

The blood-urea began to fall with the rise in urinary output on the day after the first adrenaline drip, and soon fell from 115 to 25 mg. per 100 ml. and remained at this level.

Bacteriological examination of blood and sputum revealed no specific infecting organism.

Those with experience of toxic peripheral circulatory collapse as severe as it was in this patient must have been impressed by the inadequacy of the conventional methods of treatment. Some of us who have used extracts of suprarenal cortex and its equivalent have found them of little avail in similar cases.

The dosage of adrenaline used in this case—i.e., 285 c.cm. of 1/1000 adrenaline hydrochloride—appears colossal in comparison with that of common usage.

We want to thank Sister J. N. Gibson and her staff for their care and attention of this case in an already very heavy medical ward; Prof. T. J. Mackie and the staff of the bacteriological department, Edinburgh University, for checking the bacteriology; and Air Commodore F. N. B. Smartt, medical superintendent of the hospital, and the Department of Health for Scotland, for permission to publish these notes.

Preliminary Communication

INDUCTION OF BRONCHOGENIC CARCINOMAS IN MICE

THE increased incidence in recent years of lung cancer in man has stimulated research into the induction of pulmonary tumours in laboratory animals by means of carcinogenic hydrocarbons and other compounds, with the object of elucidating the ætiology of the disease. Pulmonary tumours in animals have been difficult to obtain, however, because the delicate lung tissue is unsuitable for direct injection of carcinogenic substances. Thus experimental lung tumours have hitherto been induced by administering a carcinogen at some remote site by painting it on the skin, by injecting it intravascularly, intraperitoneally, or intratracheally, or sometimes by including it in the diet.

The object of this communication is to describe a technique of inducing tumours by the direct application of carcinogenic compounds, sometimes in combination with synthetic hormones, to adult lung tissue growing as homologous grafts in host animals. The pathology of the induced bronchogenic carcinomas will also be described.

Technique

Small pieces of adult lung are isolated under a dissecting microscope and impregnated with a few crystals of 20: methylcholanthrene. On placing the carcinogen in direct contact with the tissue to be grafted, care is taken to wrap the tissue round the crystals so that they are shielded from contact with the tissues of the host. The grafts are implanted subcutaneously, with a Bashford transplanting needle, on each side of the belly of the host. As many as six subcutaneous primary grafts have been made in a single mouse. In all cases the graft folliculitis and much seropurulent exudate in temporal and occipital regions. Pinnæ crusted; scaly erythematous patch behind right ear; drum normal. A few follicular pustules on beard area. Some blepharitis on left side. A few comedones over sternum. On forearms, groins, and backs of legs were infiltrated erythematous plaques, centrally slightly scaly, superficially resembling psoriasis but without a psoriatic reaction on grattage and with non-greasy scales, tending to be partially detached at their periphery. Follicular somewhat hyperkeratotic papules on backs of hands. Nails, lips, buccal mucosa, and tongue normal.

On re-examination (Jan. 24) yellow colour of skin had almost disappeared. Scalp heavily crusted all over, and hairs matted together. There had been a patchy hair-fall. Ears swollen, erythematous, and covered with greasy scales. Fading but brownish pigmented erythematous disks on forearms; a brownish-yellow pigmented macule on back of right hand. Behind right knee was a lichenified plaque; and there were bluish-brown areas in right groin and on calves.

DISCUSSION

There seems to be little doubt that this is a case of eczematous and pigmentary lichenoid dermatitis following the taking of mepacrine. It may be said to have resembled at various stages psoriasis, keratosis follicularis, seborrhœic dermatitis, contact dermatitis, and patchy eczematisation; and a patchy alopecia appears to be developing beneath the heavy crusts on the scalp.

A therapeutic test with mepacrine was not carried out owing to the chronicity of the condition, which has already lasted seven months, and the patient's objection to a test which, if positive, would lead to an exacerbation.

Skin tests are reported by Sulzberger (1945) as usually negative, except in eczematous or exfoliating cases.

The onset about six months after starting to take mepacrine, and the use of "booster" courses, suggests cumulative action and saturation rather than idiosyncrasy. Owing to the rarity of the condition among mepacrine takers, it seems that in most persons the cumulative dose is higher than the prophylactic dose of 0·1 g. daily, though it is also possible from slow excretion that toxicity may arise at this level in some people.

The U.S. Army physicians (1945) state that cutaneous reactions have been more frequent in persons who have taken suppressive atebrin in larger doses than the recommended amount, 0·7 g. a week, and that, in clinical treatment of malarial attacks with atebrin, routine dosage should not exceed 2·8 g. in 7 days.

This patient took 3·1 g. in the first 7 days and, after continuing with 0·7 g. each week, on three further occasions raised the dosage to 1·7 g. or even 2·3 g. in 7 days.

He was emaciated at the time of onset, and his diet of little meat, milk, fat, or fruit, but many boiled puddings and potatoes suggests that there may have been a general relative deficiency of vitamins. Keratosis follicularis is regarded as a manifestation of deficiency of vitamin A and possibly of C, while seborrhœic dermatitis seems to have some relationship to deficiencies of the B group. The tendency to follicular involvement, resulting in an appearance closely resembling seborrhœic dermatitis, is comparable to the affection of the follicles in many cases of toxicity arising from organic arsenicals, gold, and the sulphonamides.

Treatment is unsatisfactory, but consists in withdrawal of the drug, an adequate diet with vitamin supplements, and the use of penicillin and other agents to combat secondary infection, during the time necessary for excretion of the drug. Nisbet (1945) used systemic penicillin in the generalised eczematous cases. It is essential to use only bland surface applications to avoid the risk of a superimposed dermatitis medicamentosa, but fractional doses of X rays may be necessary for the control of some of the more lichenised patches.

According to Schmitt et al. (1945), intravenous sodium thiosulphate appears to have no effect on resolution. The use of parenteral crude liver extract is advisable in view of the possible presence of hepatitis and as a prophylactic against, or treatment of, lesions su vitamin deficiency.

SUMMARY

A case of eczematous and pigmentary lic dermatitis is reported, which appears to be related to mepacrine administration and avitaminosis.

The probability of cumulative action of mep from high dosage, leading to toxic effect is apparent, and there is no evidence of idiosyncrasy.

Treatment includes withdrawal of the drug, bland applications, penicillin, and vitamins.

The incidence is very low with the recomme suppressive dosage of 0·1 g. daily, and this dose should not be exceeded, unless the patient is under supe

LAW JUNCTION HOSPITAL, CARLUKE, LANARKSHIRE

IN the case described here very large doses of adrenaline were given in the treatment of acute toxic peripheral circulatory collapse. Though such treatment seems so simple, we have not been able to find any similar record. Perhaps this is because the method has been used before and found wanting.

At 6 P.M. on June 24, 1946, a German prisoner-of-war, aged 35, was admitted to the Law Junction Hospital with a letter from his camp medical officer saying that he had been taken ill at about 7 A.M. with intense abdominal pain and vomiting. Food poisoning had been diagnosed.

He was heavily built and thick-necked, with well-developed arms and chest. He appeared moribund, with lilac grey skin, dry brown tongue, and sordes-covered lips and teeth. His breath was foul, and his face, hands, wrists, ears, and feet were cyanosed. His skin blanched to the slightest touch, fingerprints being left many seconds after the examining hand had been removed. His general appearance recalled the profound collapse seen in bubonic or septicæmic plague.

His abdomen was tender in all parts: there was rigidity in the epigastrium, and he was exquisitely tender over the upper part of the left rectus, where guarding was pronounced. His heart sounds were inaudible. All over both lungs there were patches of tubular breathing which seemed at first to be most marked in the left upper lobe, but one of us thought that pneumonic sounds were most marked in the lower part of the right upper lobe. This opinion was later supported by radiography. His blood-pressure (B.P.) was 50/25, and his pulse almost imperceptible.

Reflexes in limbs and eyes were all present, if sluggish. Temperature 102°F, pulse-rate 112, and respirations White-cell count 11,700 per c.mm. (polymorphs 81%, many of them immature forms).

Diagnosis

Owing to the onset of his illness with vomiting and epigastric pain and his acute upper abdominal symptoms, an abdominal catastrophe, such as perforation, leaking, dissecting aneurysm

Among the series of pulmonary tumours in group II ccurring in strain-A mice, all were squamous-celled rcinomas except two which were malignant adeno-rcinomas.

All the tumours in the C3H mice, irrespective of whether e grafts had been treated with the carcinogen alone r plus stilbœstrol, were squamous-celled.

The primary tumours arising in grafts 12–15 weeks fter implantation in either strain consist of patches f normal collapsed lung alveoli with adjacent areas howing malignant changes well established. In a rimary squamous-celled carcinoma arising $12^1/_2$ weeks fter implantation in a strain-A mouse the squamous nd polygonal neoplastic cells have prickle borders and he surface cells are forming keratin pearls. Fig. 4 llustrates an adenocarcinoma of which some areas are ifferentiated to form gland-like structures, after con-aining an exudate of fibrin and leucocytes. There is onsiderable variation within the primary tumours, with n overall tendency to squamous metaplasia. In group II small hard subcutaneous nodules induced from lung rafts impregnated with the carcinogen and stilbœstrol vere palpable as early as 9 weeks after implantation. n their general histology they resemble the tumours nduced in both strains of mice with methylcholanthrene lone, except one tumour which was an undifferentiated arcinoma composed mainly of "oat cells." The emaining lung tumours were all squamous-celled arcinomas, except two which were adenocarcinomas. A brown induration of the lung tissue, similar to that seen in human cases of chronic and passive congestion, due to hæmosiderin, is present in some areas of the early grafts.

DISCUSSION

There are several advantages in this method of tumour induction which permit a closer study of carcinogenesis in the various tissues comprising an organ like the lung than is possible with other well-known techniques. The carcinogen is placed in direct contact with the living cells of the graft, without the use of a solvent, and therefore there is little or no foreign-body reaction, or residue of necrosis, which might mask or conceal areas where neoplastic changes first arise. Since the focus of activity of the carcinogen is within a graft and not, for instance, in some part of a large organ, the growth of the affected tissues may be more readily observed macroscopically and more easily removed for histological examination of the early stages. The neoplasms arise in subcutaneous grafts and are maintained by subcutaneous transplantation. A series of grafts established in one host can be regarded as growing under identical hormonal conditions. With other techniques the application of the carcinogen may involve changes in organs or tissues throughout the body and not necessarily only in the region where a tumour is induced. Effects of this kind may complicate the interpretation of the incidence of experimental tumours. Thus Dunlap and Warren [5] found that, in Swiss mice injected subcutaneously with carcinogenic hydrocarbons, the incidence of primary pulmonary tumours was higher in mice which had also developed tumours at the site of inoculation.

For reasons which are still obscure more difficulty has been experienced in obtaining malignant tumours from subcutaneous lung grafts impregnated with methylcholanthrene than with grafts of adult prostatic epithelium, which in strain-A mice may give a yield as high as 98% of malignant tumours.[1] Since the tumours which are obtained in lung grafts have been found to arise from bronchial epithelium, it is possible that some grafts fail to develop tumours because the amount of this epithelium in a particular graft is insufficient, or its location is unsuitable for direct contact with the carcinogen. Obviously in some individual grafts the bronchioles may be damaged in isolating the fragment, or there may be a partial failure of vascularisation.

The success obtained with grafts of prostatic epithelium from adult mice must be partly due to the use of a closely inbred strain of mice in which homologous grafting is much better tolerated than in mixed strains.[1] There is no obvious reason associated with the graft-host relationship why prostatic epithelium should flourish, whereas lung tissue implanted under similar conditions does not always survive. Without further experiments it is difficult to explain the increased tumour incidence in lung grafts of C3H mice impregnated with stilbœstrol in addition to the carcinogen. The œstrogen may stimulate proliferation of bronchial epithelial cells, which thereby become more susceptible to the action of the carcinogen, or the hormone may itself be mildly carcinogenic. Failing direct action of this kind, it is possible that œstrogen favours more rapid vascularisation of the graft, or in some way influences tumour formation by first becoming absorbed into the general circulation.

So far as I am aware, there is no evidence that bronchial epithelium, in animals treated with œstrogen over a long period, shows any pathological changes. Experiments are being undertaken to determine if stilbœstrol alone has any stimulating action on the bronchial epithelium in lung grafts.

The neoplastic influence of œstrogens is now well established for various organs and tissues, such as the mammary gland, lymphoid tissue, testis, bone, and adenohypophysis. What may be more significant in the present problem is the fact that non-specific cancer may arise from suitable dosage with sex hormones.[6,7] In other words, tissues which are not usually regarded as responding in some specific way to substances like œstrogens—and among these we must presumably include lung epithelium—do undergo neoplastic changes if œstrogen treatment is prolonged. Burrows [8] has found, moreover, that subcutaneous sarcoma induced by œstrogens cannot be due simply to mechanical injury produced by the injection or to the action of the solvents in which the œstrogen is administered. It seems significant in these experiments that no response to the carcinogen was obtained from the lung alveoli, and that, if an alveolar epithelium exists, it should remain entirely quiescent while the closely adjacent epithelium of the bronchioles proliferated in so striking and specific a manner. These observations support the view of those, such as Barnard and Day,[9] who contend that there is no epithelial lining to the lung alveoli. Further experiments with this technique should provide additional information on this problem.

SUMMARY

Bronchogenic carcinomas were induced in mice of strains A and C3H from subcutaneous grafts of adult lung tissue impregnated with 20 : methylcholanthrene.

In mice of strain C3H the tumour incidence was increased if the lung grafts were impregnated with stilbœstrol in addition to the carcinogen.

The pathology of the pulmonary tumours is described, and the action of œstrogens on the bronchial epithelium in lung grafts is discussed.

I wish to thank Prof. W. G. Barnard, of St. Thomas's Hospital medical school, and Dr. B. D. Pullinger, of the Imperial Cancer Research Fund, for their encouragement and helpful criticism.

tissue was taken from mice aged 3 months belonging to the same strain as the hosts in which the grafts were to be implanted.

I have previously reported[1] the induction of transplantable glandular carcinomas of the prostate in mice by this technique, which is a modification of that used by Greene,[2] Rous and Smith,[3] and Rous,[4] with the important difference that adult, not embryonic, tissue was used for the grafts.

Results

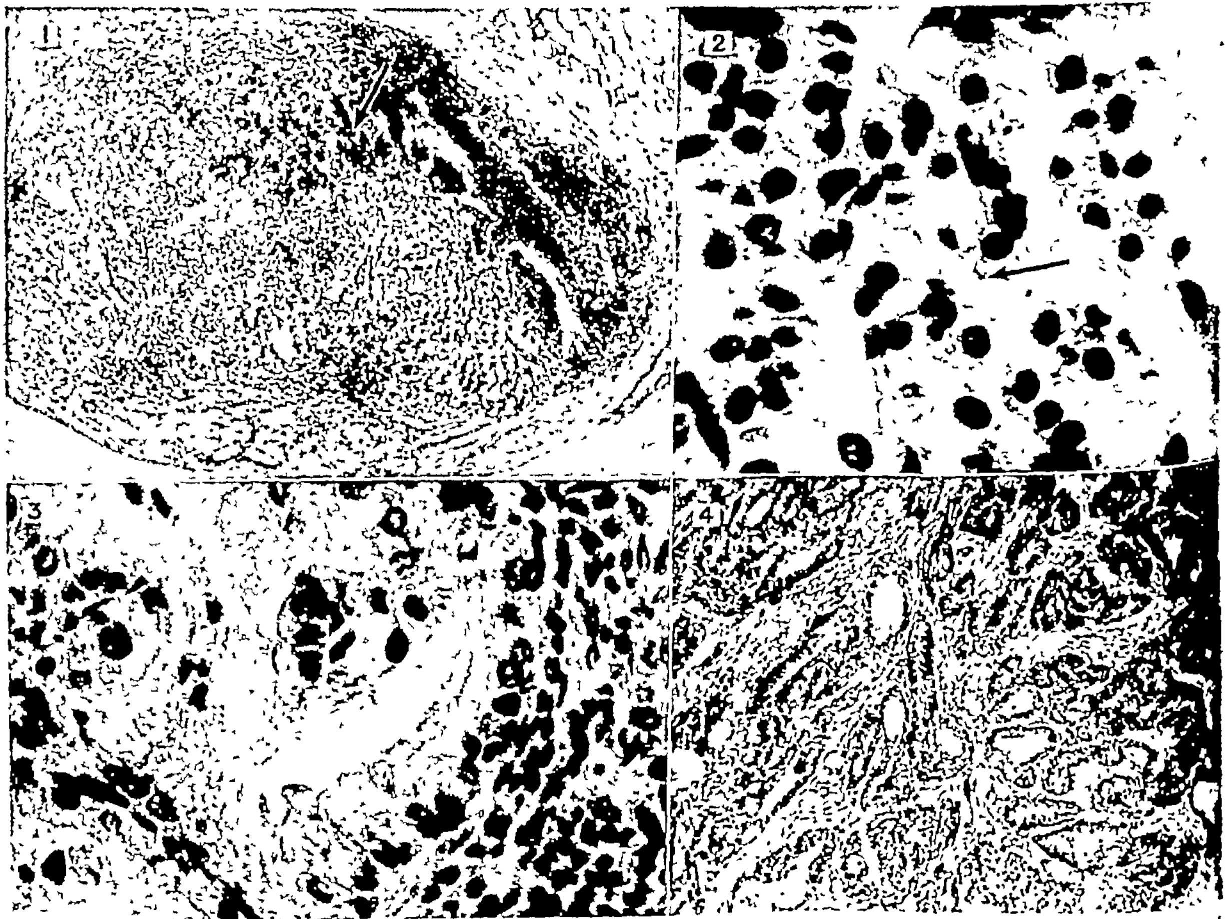
The host mice bearing lung grafts were divided into three groups. Group I were mice of strains A and C3H which received lung implants impregnated with methylcholanthrene and were killed after an interval of 6–8 weeks, before malignant tumours had developed. The grafts were fixed for histological examination of the early phases of carcinogenesis. The details of groups II and III are as follows:

Group	*Substances included with the graft*	*Strain*	*Total no. bearing grafts*	*No. which developed tumours*
II	methylcholanthrene	A	36	12
		C3H	36	5
III	methylcholanthrene and stilbœstrol	C3H	36	25

The pulmonary tumours were induced in both and female mice, the incidence being about equal two sexes. The malignancy of the tumours was cases proved by transplanting portions of the tumour into mice of the same strain. All the tra grow, and some of these tumours are now in the and fourth generations of transplantation. Grafts did not develop tumours had become necrotic, ably owing to failure of vascularisation.

Microscopic Structure of the Tumours

Examination of the primary grafts from revealed the early phases of tumour formation and that the tumours were derived from the epitheli of the bronchioles—i.e., they were bronchogenic t (fig. 1). Many of the primary grafts showed ad lying adjacent to patches of collapsed lung As might be expected, there was considerable v in these early stages of tumour formation. neoplastic cells, for instance, contained mucus; cytoplasm was foamy or distended with secretion, nuclei were large and deeply staining (fig. 2). primary adenomas appeared to lack secretory though they were arranged in alveolar-like m cells with similar darkly staining nuclei and cytoplasm. In some areas of the grafts the c epithelial cells had persisted, indicating that the implants had been maintained in a surprisingly condition (fig. 3).



Photomicrographs of sections of adult lung grafts, from strain-A mice, impregnated with 20 : methylcholanthrene and implanted subcutaneously into the belly of strain-A mice aged 3 months.

Fig. 1—Eight weeks after implantation ; arrow indicates adenoma lying adjacent to bronchial epithelium, from which the tumour arose ; patches of collapsed lung alveoli also evident ; whole implant surrounded by muscle. (× 78.)

Fig. 2—Adenoma from lung graft 8 weeks after implantation; cytoplasm of tumour cells is foamy, many being distended with secretion, as indicated by arrow; nuclei large and deeply staining. (× 550.)

Fig. 3—Section through bronchial epithelium of lung graft 7 ½ weeks after implantation ; ciliated epithelium persists, indicating healthy condition of graft. (× 375.)

Fig. 4—Primary lung adenocarcinoma which arose 12 ½ weeks after implantation ; this tumour grew on transpla into mice of the same strain. (× 87.)

‘OXYCEL’

(Oxidized Cellulose)

Hæmostatic and Absorbable

‘Oxycel’ is oxidized cellulose in sterile non-irritating gauze-like form. It is intended for the control of hæmorrhage encountered in various surgical procedures including neurological, urological, abdominal and gynæcological surgery.

Applied to bleeding surfaces, ‘Oxycel’ effects prompt hæmostasis and when left in contact with tissue it is slowly absorbed

‘Oxycel’ is supplied as individual sterile pads, each in a glass vial.

Reviews of Books

Essays on Human Evolution

Sir ARTHUR KEITH. London: Watts. 1946. Pp. 224. 15*s*.

IN these essays Sir Arthur Keith may not satisfy all his hungry critics, but his thesis is worked out in a logical manner. However controversial, the essays are stimulating, being a sincere effort to solve the riddle of human life and endeavour. Sir Arthur seems to make the duality of human thought and action the basis of much of his argument in reference to tribes and nations, though he passes rather lightly over its personal and individual implications. He divides this duality into two main elements—the ethical or moral code, and the cosmical code. The first is concerned only with the internal welfare and satisfaction of the tribe, and is pacific; the second with the external relations with other tribes and is often the origin of enmity, jealousy, and war. Tribalism, he contends, is nature's method of bringing about the evolution of man. But if this duality affects the tribe as a whole it also affects—even more, in the view of some thinkers—the outlook of the individual. MacNeile Dixon, for example, held that the whole universe displayed a dual personality: life for the individual was an endless dialogue consisting of meetings and partings, love and hate, hope and fear. "Look when you will," he said, "the contraries and antinomies confront you." They correspond with something in the universe itself, and foster, in the individual, the development of personality and character. To some disaster and disappointment means the renewal of hope; to others it means despair. Frustrations occur daily in the life of individuals even while the ethical code of the tribe and nation is in operation and maintained. According to Sir Arthur Keith, a nation cannot cease to be ambitious and competitive, for there is no cheap road to peace. When the cosmical code comes into action, with its enmity complex, the moral code is relegated to a secondary place, the security of the tribe or nation being placed first; in other words, war becomes necessary to preserve the tribe as an evolutionary unit. In this sense, he suggests, war serves a beneficent purpose. He opposes the views of T. S. Eliot and Elliot Smith that civilisation is responsible for all wars, for war in some form existed long before the dawn of civilisation. Civilisation has merely added many monstrous horrors, by-products of the scientific mind. It is only when we assume, he concludes, that evolution aims at the production of societies, not individuals, that we reach a satisfying explanation of man's dual mentality.

Spezielle Chirurgische Therapie für Studierende und Ärzte

Dr. MAX SAEGESSER, Privatdozent für Chirurgie, Berne. Berne: Hüber. 1946. Pp. 884. Sw. fr. 80.

THIS is virtually a manual of operative surgery and is written chiefly for inexperienced surgeons. It covers most of the field of general surgery, includes a full and detailed section on fractures, and omits all gynæcology and otorhinolaryngology. The chapter on brain surgery is confined to the complications of trauma and the injection treatment of trigeminal neuralgia, but that on the spinal cord describes the removal of tumours and the operation for lesions of the intervertebral disks, and in another place is given Dandy's intradural rhizotomy for spastic torticollis.

Dr. Saegesser's approach is essentially practical and he sets out to avoid academic issues as far as possible. Though he admits that there are many answers to every surgical problem, he maintains that there is only one really good answer, and accordingly he gives only one operation for each condition he describes. This has the great advantage of simplicity, and increases the value of the book for the junior surgeon who seeks straightforward authoritative guidance and who is not qualified to choose between several methods. Moreover, it ensures consistency throughout the book, for nearly all the operations described are those actually used by the author himself.

The standard of the book is high. The indications for operation are made clear and definite—indeed sometimes over-simplified—and though the author might be described as an interventionist he often gives wise words of caution. The descriptions of operative procedure are good and are illustrated by many excellent drawings. Postoperative treatment and complications are given in detail. Some defects, however, may be mentioned. The chapter on burns is far below the general level: it does not mention the dangers and disadvantages of tanning, or the indications for plasma transfusion or skin-grafting. In the section on the postoperative management of appendicitis, the surgeon is happily compared to a midwife who stands by and directs a normal process of spontaneous development; yet a régime is recommended in which measures to restore intestinal activity start as early as the day after operation. In gastric surgery entero-anastomosis and the Y-anastomosis of Rowe are both recommended without due warning of their danger.

Human Factors in Air Transport Design

ROSS A. MCFARLAND, PH.D. Division of Research, Graduate School of Business Administration, Harvard University. New York and London: McGraw-Hill Book Company Inc. 1946. Pp. 670. $6.

THIS reliable and readable book is based on observations made by Dr. McFarland as physiological adviser to certain firms in the aircraft industry and to various civilian air lines in the United States. He believes that the future of air transport depends on passenger comfort, crew efficiency, and operational safety; and his aim is to provide the aircraft designer and aeronautical engineer with existing information on human requirements. Since, however, he is inclined to assume that the reader knows the principles of physiology, the book will appeal more to the physiologist working in the field of aviation medicine than to the aircraft designer or engineer. In his enthusiasm, he tends to obscure essentials by introducing a mass of physical data more likely to confuse the reader than to clear the ground for him. This is evident when he is discussing the importance of a clear view from the cockpits of transport used on airports with heavy traffic or restricted landing areas. To support this sensible suggestion an "index of landing" is defined, based on six assumptions, the use of trigonometry, a study of the geometry of the cockpit, and the construction of an elaborate graph. A designer would be more likely to give the pilot a clear view if told about the experiments which show that a pilot becomes tired more quickly, and therefore more liable to cause an accident, if his field of vision is obstructed or reduced.

The problem of controlling noise in aircraft cabins is particularly well treated, and supported by an excellent and brief account of the physical characteristics of sound and the physiological and psychological effects which it produces. He emphasises the importance of a standard cockpit lay-out, so that the position, shape, and colour of all control levers will be similar in different types of aircraft. And pilots will agree with him that all the dials should be clearly visible on the instrument panel and their positions consistent in all types of aircraft. The first-class section on illuminating the cockpit contains an accurate account of the factors influencing dark adaptation. He recommends that the blood of air-crews should be periodically tested for carbon monoxide by the up-to-date Scholander-Roughton micro-gasometric method. The permissible standard of carbon-monoxide contamination in the aircraft, however, is expressed merely as 0·003%—not as a percentage of the total barometric pressure which ensures that the permissible concentration does not rise with altitude.

La digitale et les strophantines (*Paris: Masson.* 1946. Pp. 206).—This monograph, outlining in considerable detail Prof. D. Danielopolu's distinctive views on the action of the digitalis group of drugs, will be read with interest by many cardiologists and pharmacologists. For some 40 years he has been contributing a steady stream of articles on this particular subject, and his views, even though they have not been generally accepted in this country, are stimulating and constructive. He lays stress on the value of strophanthus, a drug that has never been sufficiently used in England.

THE LANCET

LONDON: SATURDAY, AUGUST 9, 1947

Food

This country is now confronted with food cuts ich will be generally unwelcome. If next year we d ourselves obliged to reduce the cost of our ports by several hundred million pounds there will further cuts which will make our present manner living look luxurious. Whatever happens, we nnot hope for any early return to the former abunnce of imported food, and major adjustments will obably be necessary if we are to maintain—let one improve on—present standards of nutrition. ie case for devoting more of our resources to the oduction of food at home has been plainly stated in ese columns,[1] and so has the argument that salvan will best be found by facing the facts and trying change the national food habits.[2] To face facts, wever, it is necessary to know them, and if the overnment have any wish to secure the support of e medical profession for their food policy they will ve to give us more of the data on which that policy based. The recent controversy on whether or not e national nutrition is deteriorating was made not ly useless but positively harmful by the Government's unwillingness to part with information which ey must certainly possess: and in the absence of this formation doctors in general, whose words on diet ive some weight with the public, continue to speak terms of prejudice and personal impressions The inistry of Food not only could give us recent figures r the amount of food moving into consumption, and ie average calorie consumption deducible therefrom, it could divulge the proportions taken up by the rious sections of consumers, such as expectant and ursing mothers, children, or invalids, and the nounts distributed as domestic rations, through nteens and restaurants, and as school meals. 'e could have full publication of the results of the rvey of family food purchases about which occaonal figures have from time to time been divulged Parliament. All this statistical information is ssential before a reasoned opinion on the national od position can be formed. But of greater interest the medical profession would be a statement on ie surveys which are known to have been undertaken f the diets which are today actually eaten by houseives, by adolescents, by industrial workers, and y other categories. A clinical assessment of nutrition annot be satisfactorily made when, as is the case this country, the level of food consumption is at ast sufficient to prevent deficiency symptoms. Short f such deficiency, however, there may be reduction physiological efficiency. Hence it is doubly mportant that the information available on the utrition of the population should be published. The verage weights of school-children of certain ages in iverpool and Glasgow are apparently ceasing to rise: hat changes are occurring in the weights of dults?

So long as the Ministry could be sure of continuing to supply food which in quantity and variety gave general satisfaction there was perhaps some reason to regard explanation as a waste of time. But when the fare it offers may no longer suffice for sound nutrition, it would certainly be well advised to take the medical profession into its confidence.

Differential Diagnosis of Jaundice

It is a pity that all attempts to clarify the pathology of icterus seem to involve some new system of classification. One tends to distrust systems, especially new ones, feeling them to be suitable only for examination purposes. Nevertheless any interpretation of a symptom must evolve from the complex to the simple—from investigation and discussion to system —and **With**'s summary of the pathogenesis of jaundice[1] is no exception.

His schema of three "ideal" forms of jaundice is based on recent work which has invalidated some of the earlier hypotheses. Thus the ability of the van den Bergh test to distinguish bilirubin which has been actively excreted by the liver cells is now doubted.[2] Jaundice due to over-production of bilirubin so great that the liver cannot handle it is almost certainly a myth; hæmolytic jaundice is associated with increase of circulating bilirubin, but it is the coincident damage to liver cells from anoxia and other causes which prevents adequate excretion. Obstructive jaundice does not seem to be entirely, or even principally, caused by the bursting of engorged bile capillaries and the overflow of bile into the lymph-spaces. **Shafiroff** et al.[3] controlled the intrabiliary pressure in dogs, and found that below 25 cm. of water no bilirubin appeared in the blood or the lymph from the thoracic duct; at 30 cm. of water half the dogs showed bilirubin in blood and lymph, but half of them in the lymph only; above 40 cm. of water pressure the blood and lymph of all dogs contained bilirubin. **With** assumes that rupture of bile passages at a pressure of 25–30 cm. of water is unlikely, that simple diffusion across the walls of bile capillaries is also very unlikely because of compression of the lymph-spaces of Desse, and that liver cells may in some circumstances secrete bilirubin actively into the lymph channels as well as into the bile channels. The same results might be found if damage to the bile canaliculi produced stretching and increased permeability, as suggested by **Watson**.[4] Actual rupture may, however, take place when high pressure and consequent necrosis have persisted for a long time. Again, jaundice due to hepatitis need not arise from retention and inability of damaged liver cells to excrete bilirubin. It is far more likely, **With** believes, that the necroses demonstrated by **Iversen** and **Roholm**,[5] in material from liver punctures, open bile spaces and allow bile to drain into the lymphatics. The "ideal" types he suggests as a basis for classification are (1) the type due to over-production of bilirubin, which cannot occur alone; (2) the type due to under-excretion from inability to extract bilirubin from the blood; and (3) that due to passage of bile into the lymph, either actively or passively, and so into the blood The

penicillin nonad tulle

The efficacy of the local application of penicillin has been established by its use in the forms of powders, solutions, creams, and ointments. A new development is the introduction of Penicillin Nonad Tulle. This non-adherent sterilized gauze dressing of wide mesh is impregnated with an emulsifying base of soft paraffin and anhydrous lanoline, containing 1,000 units of penicillin per gram.

Submitted for trial in hospital practice, including special branches of surgery, Penicillin Nonad Tulle has been welcomed as a dressing for infected wounds and burns and for operation wounds, including those of eyes, ears, and nose, and those of skin-grafting.

PENICILLIN NONAD TULLE

In tins containing 10 pieces each 4" × 4", 5/3.

Food

THIS country is now confronted with food cuts ich will be generally unwelcome. If next year we d ourselves obliged to reduce the cost of our ports by several hundred million pounds there will further cuts which will make our present manner living look luxurious. Whatever happens, we nnot hope for any early return to the former abun- nce of imported food, and major adjustments will obably be necessary if we are to maintain—let one improve on—present standards of nutrition. e case for devoting more of our resources to the oduction of food at home has been plainly stated in ese columns,[1] and so has the argument that salva- n will best be found by facing the facts and trying change the national food habits.[2] To face facts, wever, it is necessary to know them, and if the vernment have any wish to secure the support of e medical profession for their food policy they will ve to give us more of the data on which that policy based. The recent controversy on whether or not e national nutrition is deteriorating was made not ly useless but positively harmful by the Govern- ent's unwillingness to part with information which ey must certainly possess: and in the absence of this formation doctors in general, whose words on diet ve some weight with the public, continue to speak terms of prejudice and personal impressions The inistry of Food not only could give us recent figures r the amount of food moving into consumption, and e average calorie consumption deducible therefrom, t could divulge the proportions taken up by the rious sections of consumers, such as expectant and rsing mothers, children, or invalids. and the nounts distributed as domestic rations, through nteens and restaurants, and as school meals. e could have full publication of the results of the rvey of family food purchases about which occa- onal figures have from time to time been divulged Parliament. All this statistical information is ssential before a reasoned opinion on the national od position can be formed. But of greater interest the medical profession would be a statement on e surveys which are known to have been undertaken f the diets which are today actually eaten by house- ives, by adolescents, by industrial workers, and other categories. A clinical assessment of nutrition annot be satisfactorily made when, as is the case this country, the level of food consumption is at ast sufficient to prevent deficiency symptoms. Short f such deficiency, however, there may be reduction n physiological efficiency. Hence it is doubly mportant that the information available on the utrition of the population should be published. The verage weights of school-children of certain ages in iverpool and Glasgow are apparently ceasing to rise: hat changes are occurring in the weights of dults?

So long as the Ministry could be sure of continuing to supply food which in quantity and variety gave general satisfaction there was perhaps some reason to regard explanation as a waste of time. But when the fare it offers may no longer suffice for sound nutrition, it would certainly be well advised to take the medical profession into its confidence.

Differential Diagnosis of Jaundice

IT is a pity that all attempts to clarify the pathology of icterus seem to involve some new system of classification. One tends to distrust systems, especially new ones. feeling them to be suitable only for examination purposes. Nevertheless any interpretation of a symptom must evolve from the complex to the simple—from investigation and discussion to system —and WITH's summary of the pathogenesis of jaundice[1] is no exception.

His schema of three "ideal" forms of jaundice is based on recent work which has invalidated some of the earlier hypotheses. Thus the ability of the van den Bergh test to distinguish bilirubin which has been actively excreted by the liver cells is now doubted.[2] Jaundice due to over-production of bilirubin so great that the liver cannot handle it is almost certainly a myth; hæmolytic jaundice is associated with increase of circulating bilirubin, but it is the coincident damage to liver cells from anoxia and other causes which prevents adequate excretion. Obstructive jaundice does not seem to be entirely, or even principally, caused by the bursting of engorged bile capillaries and the overflow of bile into the lymph-spaces. SHAFIROFF et al.[3] controlled the intrabiliary pressure in dogs, and found that below 25 cm. of water no bilirubin appeared in the blood or the lymph from the thoracic duct; at 30 cm. of water half the dogs showed bilirubin in blood and lymph, but half of them in the lymph only; above 40 cm. of water pressure the blood and lymph of all dogs contained bilirubin. WITH assumes that rupture of bile passages at a pressure of 25–30 cm. of water is unlikely, that simple diffusion across the walls of bile capillaries is also very unlikely because of compression of the lymph-spaces of Desse, and that liver cells may in some circumstances secrete bilirubin actively into the lymph channels as well as into the bile channels. The same results might be found if damage to the bile canaliculi produced stretching and increased permeability, as suggested by WATSON.[4] Actual rupture may, however, take place when high pressure and consequent necrosis have persisted for a long time. Again, jaundice due to hepatitis need not arise from retention and inability of damaged liver cells to excrete bilirubin. It is far more likely, WITH believes, that the necroses demonstrated by IVERSEN and ROHOLM,[5] in material from liver punctures, open bile spaces and allow bile to drain into the lymphatics. The "ideal" types he suggests as a basis for classification are (1) the type due to over-production of bilirubin, which cannot occur alone; (2) the type due to under-excretion from inability to extract bilirubin from the blood; and (3) that due to passage of bile into the lymph, either actively or passively, and so into the blood. The

novelty of his approach to the mechanics of bilirubin excretion, with its division of jaundice into production, retention, and lymphogenous types, lies in the introduction of the lymphogenous type, whose existence or non-existence (as he acknowledges) is susceptible of experimental proof. Combinations of these three types can be made to account theoretically for the sometimes contradictory findings in man. But, if faith in the van den Bergh reaction is to be undermined, something more than a new classification of jaundice is needed as a diagnostic aid; and this With does not provide. The only pointer which emerges from his hypothesis is that in lymphogenous jaundice the plasma bilirubin is always as high as 10–20 mg. per 100 ml.

Since so-called hæmolytic jaundice seldom causes difficulty, the important problem confronting the clinician is, as Schiff [6] observes, the distinction between obstructive jaundice and hepatitis, the surgical treatment for the one often being fatal in the other. This distinction is not made easier by the existence of a small group of cases of hepatitis, mainly arsenical in origin, which appear to have intrahepatic obstruction and in which biochemical tests show the results obtained with complete obstructive jaundice.[7] The attacks of jaundice, and many other symptoms of hepatitis, may closely resemble those of biliary obstruction. Despite the champions of the various function tests, it remains true that diagnosis can only be satisfactorily attempted if a full clinical picture of both obstructive jaundice and *hepatitis is present in the mind of the diagnostician*, and in this connexion the conclusions of Kelsall, Stewart, and Witts on another page of this issue are helpful. They draw attention to the great range of severity of the pathological process in hepatitis, showing that jaundice may or may not occur in the acute phase, and that a similar variability of symptoms, interspersed with complete remissions, is seen in the subacute and chronic stages. Reviewing 35 cases, they found that a history of alcoholism was never obtained, and that the majority of patients with insidious cirrhosis were women. Some patients with the chronic condition gave histories of initial infective or chemical hepatitis, but in half the cases the ætiology was obscure, and the investigators do not permit themselves to speculate whether these may not have been due to undiagnosed infective hepatitis or nutritional disturbances in the liver.

The picture of the cirrhotic patient is sufficiently easily recognised, as is the syndrome of the preceding acute hepatitis, fully described recently by Capps et al.[8] in a study of over 2000 cases. It is the intermediate subacute or early chronic stages of the process that cause difficulty, and here the clinical pictures described by Witts and his colleagues are of assistance. Any one, or all, of the signs and symptoms of cirrhosis may appear and subsequently disappear. Jaundice, intermittent and variable, together with persistent ill health and dyspepsia, may be the presenting picture, only clarified later by the sudden appearance of ascites, hæmorrhage from œsophageal varices, or pigmentation and nævi. Before any of the more dramatically obvious symptoms arise it is sometimes impossible clinically to differentiate the picture of chronic hepatitis from that of biliary obstruction. An attempt has been made by Giansiracusa and Althausen [9] to discover the data of value in distinguishing these conditions. They reviewed 166 selected cases of jaundice and found that age-incidence, bradycardia, fever, pain in the abdomen and back, malaise with digestive upsets, and pruritus were of little use as pointers to either condition, whereas ascites and palpable gall-bladder were almost diagnostic. In their series, twice as many men suffered from cirrhosis and from obstructive jaundice as women, and nine times as many men as women developed carcinoma.

The figures given by Schiff for Cincinnati General Hospital are of interest in suggesting the relative frequency of hepatitis and neoplastic and calculous obstructive jaundice.

	Hepatitis		Neoplasm		Calculus
Over 40 (245 patients)	38·0%	..	42·0%	..	14·0%
Under 40 (575 patients)	65·0%	..	21·0%	..	6·0%

It will be seen that the other types of jaundice make up only 4–8% of the total; they include congenital abnormalities of the biliary system, hæmolytic and other anæmic jaundices of children and adults, and the entity named by Meulengracht [10] chronic intermittent juvenile jaundice. With increased attention now being focused on the atypical syndromes of infective hepatitis, it is refreshing to find that there is a class of case which suffers from marked lassitude, digestive disturbances, and fleeting icterus but which is entirely benign. Careful reference to Meulengracht's description of the condition is recommended, however, before deciding in favour of this diagnosis.

Too much reliance must not be placed on biochemical tests in jaundice, and both Schiff and Higgins et al.[11] have emphasised their variability. In a full survey of the position the latter authors recommend testing the plasma bilirubin, alkaline phosphatase, and albumin and globulin in each case, this combination of tests giving a clearer diagnostic picture than any one test used alone. Schiff holds that laboratory tests are best performed collectively and repeatedly, since jaundice is a dynamic condition and the tests will vary with the stages of the pathological processes. It is evident that, despite the assistance given by a clearer picture of the mechanism of bile secretion in disease, by careful clinical descriptions of conditions producing jaundice, and by improved laboratory aids, all the knowledge, judgment, and intuition of the clinician are still required for the diagnosis of all but the most typical syndromes in which jaundice appears.

Beds

THE *case of the man of 74, with a fractured* skull, who was refused admission to one London hospital, *was discharged after 8 days in another, and* died 4 days later, has drawn public attention to the lack of hospital beds for acute cases. There is no doubt whatever that old people, who are likely to occupy a bed for a long time, are often turned away though their condition needs urgent treatment. Thus cases of acute intestinal obstruction in elderly people ve been refused for fear the cause should prove be cancer; and serious medical conditions are nmonly refused because they may run a long urse. The London Emergency Bed Service inform that of 247 applications made through them in the st week of this year, 44 were declined admission on unds of old age; and in the first week of June the ure was 19 out of 182.

The difficulty of the hospitals is clear: they have rcely enough nurses to staff their beds, and many ve closed some of their wards or beds for lack of ff. If they are to cope with the "acute" work, ey must keep active as many beds as possible, and ey dread the long "chronic" case which will put bed out of commission for weeks or even months. the old days voluntary hospitals could send such ses on to the county hospital when the acute stage as past; but now the county hospitals, crowded and derstaffed, are themselves refusing patients; which eans that if an old person with nowhere else to go admitted to an acute ward he may block a bed definitely. As Mr. R. E PEERS, secretary of the mergency Bed Service, explained to the general press st week, the hospitals have to decide who shall have e beds, and they generally prefer to give the bed the patient with the best chance of living. It is anifest that old people should have the right of dmission to hospital no less than younger ones, if ly in order that medical science can be brought to ear on their disabilities; yet unless great care is xercised by admission officers in avoiding long-stay ases the hospital fills up with them and gradually oses its power to help the acute sick. Unfortunately, he fact that this arrangement is very reasonable does othing to mitigate the hardship involved in cases uch as the one described; and discrimination between atients in this crude way ought not to go on. If e cannot quickly get staff for our hospitals, either y a great extension of an improved part-time nursing cheme or in other ways, we must study how to use eds more economically. Could we not for example o more to ensure that hospital care is given to those ho really need it but not to those who don't?

In all this talk of lack of beds we tend perhaps to orget that nearly everyone in this country goes to leep each night in a bed of his own, and that when e falls sick no bed seems better. The concentration f consultants and diagnostic equipment in hospitals ays us open indeed to the charge of depriving the atient who is ill (but not acutely ill) of the useful nfluence of familiar surroundings; and it is worth onsidering reports of an experiment at the Montefiore Hospital, New York, where they have been trying to xtend nursing and medical care into the home.[1] Iontefiore patients are classified as those who need the pecial facilities of hospital, and those who need nly active medical and nursing care. The medical equirements of this second group are examined, and heir family and home environment is assessed efore they are sent home. Full-time doctors and full-time social worker staff the department of ome care. Medical attention is available all round he clock, and visits are made as often as the patient's ondition demands. Consultants are to be had from ll the departments of the hospital. Nursing care is given, according to circumstances, by arrangement with the Visiting Nurse Service of New York. The social service worker calls regularly and helps the family in any way required; and, when necessary, help in the home is given by local or community services. Drugs, transport to and from hospital, laboratory studies, and hospital equipment and supplies are all at the service of the patient, and he is under the same doctor whether he is at home or in the wards. The cost to the hospital of this home service works out at about $3 a day, compared with $10 a day for an inpatient. Dr. E. M. BLUESTONE,[2] director of the hospital, thinks that every general hospital should have a "department of continued care" so that it need no longer send on "unfinished business" to the hospitals intended for long-term cases. These long-term cases, moreover, should be carefully divided into those that really need permanent institutional care, and those that can be looked after in their own homes.

In this country anyone attempting to reproduce the Montefiore Hospital scheme would come up against the difficulty that patients ill at home are treated by their own home doctor, who may have no connexion with the hospital. In the National Health Service, however, we could certainly develop domiciliary care of all kinds if we decide that the apparently irresistible flow of medical work into hospital ought to be checked or reversed. A large proportion of the diagnostic services of a hospital can in fact be readily taken to the home, and Dr. HARWOOD STEVENSON,[3] in his plea for the appointment of "home consultants" to work with the local practitioners, points out that the help of a mobile technician with a portable X-ray apparatus or electrocardiograph enables one to investigate the large majority of cases on the spot. Now more familiar, though no less cogent, is the argument that far more patients should be investigated in the outpatient department instead of being taken into hospital for the purpose.[4] We hope at least that the new regional hospital boards will recognise that there can be more than one approach to this crucial problem of beds. Provision of more hospital beds may be the obvious solution; but at a time when this is virtually impracticable we shall do well to concentrate on efficient use of those we have.

The Old Paradox

IN his foreword to the annual report of the Food and Agriculture Organisation of the United Nations, Sir JOHN BOYD ORR, the director-general, writes:

> "Meanwhile the paradox of the years between the wars shows signs of being repeated. The increase of agricultural production achieved by exporting countries in their efforts to relieve the world shortage may well lead to the sudden occurrence of unmarketable surpluses. . . . Unless measures are taken in advance to deal with these surpluses, they will again bring ruin and misery to millions of land workers and will endanger the stability of the whole economic system."

In this relatively wealthy country before the war we had access to any amount of food and could afford to buy it. But now that we are, temporarily, joining the ranks of that large majority who cannot afford to pay, we have additional reason to support ORR's demand, over many years, for effective action against starvation in the midst of plenty.

Annotations

EPIDEMIOLOGY OF POLIOMYELITIS

AT the Rocky Mountain Conference on Infantile Paralysis last December Dr. Albert B. Sabin examined *unexplained features in the epidemiology of poliomyelitis*, and suggested some preventive measures. His address appears in the *Journal of the American Medical Association* for June 28.

Nothing in the history of the disease, he said, is so baffling as its change during the past fifty or sixty years from a sporadic to an epidemic condition. Better diagnosis and reporting are the result rather than the cause of increased incidence; and the fact that there are parts of the world, regardless of latitude, in which epidemics are still unknown is additional evidence of the recent origin of epidemics. Another peculiar circumstance is that epidemics have occurred most often and with the greatest severity in the very countries where sanitation and hygiene are best. Why, he asked, should paralytic poliomyelitis, with rare exceptions, remain almost dormant during more than two-thirds of the year? And why is it that when epidemics first appeared in large urban centres about 80–90% of cases were in children under 5 years of age, whereas latterly as many or more children in the 5–9 age-group have been affected?

For an analysis of these questions one must, Sabin thought, have information about the natural history of the infection in man, about the reservoir of the virus in nature, about its immunological and invasive characteristics, and about the immune response of human beings to infection. The extensive studies of the past few years have indicated that the alimentary tract and the nervous system are predominantly attacked; the virus can be found in some portion of the tissues of the alimentary tract in almost all cases of human poliomyelitis; and examination of the distribution of the virus throughout the entire body indicates that it is in the alimentary tract as the result of primary localisation and multiplication. The virus has been found to persist in the stools in 70% of cases during the first two weeks, in 50% during the third and fourth weeks, in 27% during the fifth and sixth weeks, and in 13% during the seventh and eighth weeks. During infection the virus is to be found in the pharynx but not in the nasal secretion or saliva; rarely, and then only after blowing and coughing, the virus has been detected in cloth masks worn by infected children. There is, however, still a difference of opinion on whether droplets originating from the pharynx or dissemination from infected stools play the dominant part in spreading the disease; Sabin himself considers infected stools the most likely source.

The controversy over the possibility of infected stools spreading infection has been resolved by the demonstration that strains of virus of recent human origin can produce paralytic poliomyelitis by the oral route in chimpanzees and cynomolgus monkeys without invading the central nervous system by the olfactory pathway. The abundance of the virus in stools also raises the question of the possible rôle of flies and of drinking-water. The virus has in fact been demonstrated in flies; and, though these may not be the only factor determining the increased incidence of the disease in the summer months, Sabin holds that the special seasonal character of most outbreaks may reasonably be related to the greater dissemination of the virus by contaminated flies, superimposed on dissemination through ordinary human intercourse, which has been demonstrated throughout the year. Intimate human contact, while undeniably a factor in the year-round dissemination of the virus and in the so-called radial spread sometimes seen during outbreaks, does not by itself explain the recurrent summer epidemics. Unlike certain other infections of childhood, poliomyelitis assumes epidemic form during the very months when children are away from school.

The question has long been asked: Do more people acquire poliomyelitis during the summer and early *autumn months, or is there only a difference* in the ratio between the number exhibiting the paralytic and inapparent, non-paralytic forms of the disease? Perhaps the most reliable data, in Sabin's opinion, are provided by the periodic examinations made of the same sewer line in New York; the virus has been isolated from the sewage concurrently with small increases in the number of clinical cases in the neighbourhood, but at no other times. There is no convincing evidence that the large epidemics in the United States are related to water-supply.

Flies, and some monkeys, and possibly other unidentified animals may get the virus under natural conditions from human sources; but there *is* no reason to modify the original assumption that man is the only ultimate reservoir of the organism. Perhaps the most important immunological problem is that of multiple types of virus. There is certainly more than one type; but it is *not certain whether the known strains fall into two,* three, or some indefinite number of distinct immunological types. Between 1935 and 1939 a number of workers reported that there seemed to be no correlation between an attack of the disease, or the passing of an epidemic through a community, and the appearance of neutralising antibody, as *tested for the most part against* a single standard passage strain and occasionally also against some other more *recently isolated virus*; and F. M. Burnet concluded that "poliomyelitis antibody is not a result of exposure to or infection by the virus of epidemic poliomyelitis." If this is so, the concept that poliomyelitis virus is as widely disseminated in one part of the world as in another, without reference to the occurrence of epidemics, can no longer be accepted without reservations, because it is based chiefly on the results of a small number of neutralisation tests whose significance remains doubtful. In future studies, Sabin suggested, it might be wise to test the serum from each patient against the virus isolated from his own pharynx or stools and not to assume that a single virus is responsible for a single epidemic. Among American soldiers on foreign service outbreaks have occurred without any increase in the incidence of the disease among the local population; and during the past two years the incidence among troops in the Philippines has been at least ten times as high as in the Army within the United States itself. Observers who have lived some years in China testify to the relative rarity of the disease in the native population *as against* that in white people. One possible explanation is that in some foreign countries the virus is more widespread or is of a different immunological type to that encountered in the homeland. If the virus in these countries is so widespread that infection is acquired by almost everyone in infancy, then why is infection inapparent and accompanied so seldom by paralysis? Where epidemics have appeared for the first time, 90% of paralytic cases are found in children between 1 and 5 years of age; so if there is a period of grace it is probably in the first twelve months of life. Does it follow, then, that the disease becomes epidemic in any country where large numbers of children fail to acquire the poliomyelitis virus during that important phase? If, on the other hand, it is assumed that the major factor responsible for the epidemic appearance of paralysis is biologically irrelevant mutation of the virus to an invasive type, then the different behaviour of the infection in native populations and foreign troops is inexplicable. Moreover, if the first appearance of epidemics were due *to the introduction* of new immunological types, one would not expect to find 80–90% of paralytic cases among children under 5 years ıe following facts, Sabin thinks, should govern ic-health measures during an outbreak: (1) more s is being disseminated than at other times; (2) the s is present for a short time in the throat and more ı and for longer in the intestinal tract and stools of e apparently healthy people as well as of acutely lysed patients; (3) from these sources the virus may ransmitted by intimate contact, contaminated hands, fomites, but there is no evidence that droplets emitted ı the respiratory tract play a significant part, if any, lissemination; and (4) during an epidemic the h" flies can become contaminated with the virus, which can deposit in infective amounts on food, and umption of such contaminated food can produce disease. From this Sabin deduces these opinions:

Measures designed to minimise spread by droplet infection not warranted.

Measures designed to diminish the chances of transion by contact during intimate play of children, whether chool or out of school, are reasonable and warranted. he playgrounds and swimming-pools should be closed. ools may be opened or closed, depending on whether the dence of contact among children can best be enforced r out of school. Avoidance of strenuous physical exercise lso reasonable.

Measures to minimise contamination of food by flies warranted; but attempts at mass destruction of flies of doubtful value. Efforts should, however, be made revent flies having access to sewage-disposal plants and human sewage.

Patients with poliomyelitis may be admitted to the eral wards of hospitals, but should be treated with alled "*typhoid technique*" for at least four weeks from onset of systemic disturbance. Bed-sheets, towels, and er laundry during epidemics may be regarded as potentially taminated, and workers handling laundry may be advised arding the wearing of gloves and washing of hands.

. Isolation at home of patients with poliomyelitis may sonably be continued for four weeks from the onset of nptoms. The children of such households, and older mbers who are engaged in the handling of food in stores restaurants, or whose occupation may bring them into imate contact with older children, should remain at home at least two weeks.

All these measures, Sabin concludes, are advocated not h the idea that they will stop an epidemic but rather the belief that at least some may thus escape infection o might otherwise have become paralysed.

PHYSIOLOGY OF AIRCRAFT DESIGN

IN 1878 Paul Bert[1] published an account of his periments on the effects of altered barometric pressure animals and man. This remarkable book, written a student of Claude Bernard, laid the foundations of r knowledge of the effects of altitude on the aviator, though at that time aerial ascents had only been made balloon. Almost all of Paul Bert's findings have ice been confirmed, and the principles underlying the pply of oxygen to airmen are based on his work. 1939 Armstrong,[2] a surgeon in the United States my Air Corps, published his textbook of aviation edicine, describing the effects of flight on man, and mmarising the bulk of the work on the applied ysiology of the subject up to that time. McFarland,[3] so of the United States, has now written a book eviewed on another page) on human factors in rcraft design. The aim of those who design the odern air-liners is to provide their passengers with a andard of comfort comparable to that found in trains steamers. McFarland emphasises the increasingly portant part which physiology plays in aircraft design general, though the book deals only with the physiogical problems of civil aviation.

During the late war the claims of engine and airframe came first, and it was impossible for the physiologist to influence aircraft design appreciably, his task being merely to do all he could to increase the efficiency of the air-crew. The problem of oxygen-supply was a good example of this. The ideal solution was to enclose in a pressure cabin all those who flew at heights at which oxygen was needed; but production difficulties put this out of court. The result was the design and development of an oxygen system and face-mask for all fighter and bomber crews. The position has now changed, and the function of the physiologist is to give the aircraft designer information on the changes in ventilation, temperature, and pressure which man can tolerate with comfort, so that a satisfactory pressure-cabin can be built.

As long as men fly, the performance of the aircraft will, in the final analysis, be limited by human skill and endurance. To cater for the great speeds of today, aircraft designers must have an accurate knowledge of the limitations of the human body to the stresses of flight. *Man cannot be treated as a tiresome adjunct to be squeezed into the aircraft as an afterthought*: he is the essential unit round which the aircraft is built; and Dr. McFarland approaches his subject with that in the forefront of his mind.

SURGERY IN BRONCHIECTASIS

THE basic mechanism of bronchiectasis probably lies in bronchial obstruction, followed by infection. Once established the condition becomes permanent, though there is a transitory pseudo-bronchiectasis which may follow acute infections, notably virus pneumonia. The early stages of bronchial dilatation can only be satisfactorily recognised by radiography, for the clinical picture still described in many textbooks is that of an advanced stage of the disease. Conservative treatment, which includes postural drainage, breathing exercises, and chemotherapy, plays an important part in the control of symptoms but produces little or no alteration in the bronchographic picture in established cases. Though the anatomical picture may remain static for long periods, the condition is usually steadily progressive and consequently a strong case can be made for early surgical treatment. In an analysis of 50 consecutive surgical cases Adams and Ficarra[1] emphasise both the physical and emotional disability of the disease as an indication for surgery. The tragedy of the advanced case is fully recognised but the social disability arising from continual coughing and expectoration has not always been appreciated.

The prospects of successful surgical excision depend on the amount of lung involved. Dilatation localised to one or two lobes is most suitable for lobectomy, whereas diffuse, though less advanced, dilatation is not so favourable and a balance has to be struck so that the minimal amount of lung tissue is sacrificed. In the last five or six years there have been great advances in the technique; not only has dissection lobectomy become established[2] but segmental resections are being increasingly performed.[3] Age is an important factor in the selection of cases, for the results have not been nearly so satisfactory in patients of middle age or over as in younger people; so surgery should be embarked on in older people only if the indications are unusually strong. Long pre-operative preparation, both with posture and medication, and the services of an expert anæsthetist are essential. At operation the individual elements of the lobe or segment are secured, with particular attention to the closure of the bronchus. The mass ligature technique inevitably led to infection with formation of bronchial fistulæ, and the necessary drainage of the pleural space

greatly prolonged the convalescence period. The present method of dissection lobectomy leaving a closed chest, with potential infection controlled by penicillin, requires only three or four weeks in hospital, and with intensive breathing exercises and rehabilitation an early and efficient functional cure can be confidently expected in a high proportion of cases. Of the postoperative complications, atelectasis is usually more common[4] than Adams and Ficarra imply, and pleural infection occurs in some 10% of cases.

It cannot be said that excision is an ideal means of treating bronchiectasis, but until more successful conservative measures are devised it must remain the backbone of effective therapy, and its results in localised cases are gratifying both to patient and surgeon.

PHTHIOIC ACID AND TUBERCULOSIS

It is now nearly twenty years since R. J. Anderson, of Yale, isolated three different fatty fractions—an oil, a wax, and a phosphatide—from the tubercle bacillus. Sabin subsequently studied the effects of Anderson's three fractions in animal experiments, and she and her co-workers after lengthy investigations concluded that the optically active phthioic acid produced a tissue response of epithelioid cells and giant cells resembling the cellular reactions of tuberculosis. At that stage the research languished and little more was heard of it. In his presidential address to the Royal Society last November, Sir Robert Robinson[5] in stressing the important part played by microchemistry of recent years in the field of biochemistry cited among his examples new work on the waxy envelope of the tubercle bacillus. Investigations by N. Polgar have now shown that phthioic acid, which has a formula of $C_{26}H_{52}O_2$, is 3 : 13 : 19-trimethyltricosanoic acid, a straight chain of 23 carbon atoms with 3 methyl branches. Other members of this range of synthetic branched long-chain fatty acids have now been isolated, and some of them appear to be toxic. Sir Robert Robinson laid stress on the existence of methyl groups which block β-oxidation.

These extremely complicated biochemical researches are still in their infancy, but they appear now to have reached a stage at which the pathologist may usefully take up experimentation again at the point where Sabin and her associates left it about 1930. Ungar[6] has made some preliminary experiments with phthioic acid and synthetic analogues by injecting them intraperitoneally into guineapigs, having first ascertained their general toxicity to mice. Of the 14 synthetic analogues studied, 3 : 12 : 15-trimethyldocosanoic acid (no. 270 of the series) proved to be one of the most active. Broadly speaking the lesions produced in the guineapigs were granulomatous foci (chiefly in the omentum), consisting of epithelioid cells, monocytes, and giant cells of the foreign-body and Langhans types, and having central areas of necrosis. When injected intradermally no. 270 produced a local reaction of erythema and induration. A number of these fatty acids similarly injected into tuberculous guineapigs yielded no specific response, and they had no protective action when administered prophylactically before infection with a virulent human strain of tubercle bacillus.

The human tissue reactions to fatty acids and oils seem likely to open up a new chapter in human pathology. These substances are being used extensively as vehicles for the suspension of therapeutic substances. They are also being increasingly used in industry, and the worker is being exposed to their action in various ways. The superficial resemblance of some of the cellular reactions induced to the true tuberculous lesion naturally provokes speculation. How far this work will lead us in the field of chemotherapy of tuberculosis remains to be seen. The lesions induced in man can certainly be very confusing to the clinical pathologist.

ONE AND INDIVISIBLE

THE Master of Balliol has been speaking of a growing recognition that scientists belong to one fellowship. Science, he tells us, is beginning to be in the position of the medieval Church in that it is becoming an international community, commanding respect. These words take us back to Sir Henry Dale's treatment of the theme in his remarkable Pilgrim Trust lecture the freedom of science.[2] Before the war of 1914-18, said, such a community was a substantial reality, th its influence was already being weakened by na rivalries and resentments. After that war the effort re-create the feeling of confidence and common in among the scientists of different countries could claim steady advance till in 1933 aggressive natio began its open resurgence. In the circumstances of today nobody could question the particular duty of scientists to consider whether anything can be done rescue science, and therewith civilisation, from a danger which threatens both, and Dale holds that "nothing could so much conduce to that end as a renewal of the full and intimate confidence and community of interest among the scientists of all the world; of that informal brotherhood in science, ignoring all national and political frontiers and all differences of social philosophy, which effectively existed within the memory of so many of us." As a kind of Hippocratic Oath—a formal profession of faith and conduct—which every scientist, of whatever nation, might be asked to accept, it would be difficult, he thought, to improve on Benjamin Franklin's "Do you love truth for truth's sake, and will you endeavour impartially to find and receive it for yourself, and communicate it to others?" If men of science had abided by this rule they would have made it impossible for the world to misuse science as in these recent years.

> "Secrecy, as Franklin saw, is alien to the very spirit of *science, and it is the main infection*, I suggest to you, from which science sickens today. . . . The right and the duty to tell the truth which we discover, without regard to the interest of any person, prejudice, creed, political theory, or national policy has been the central item in the charter of our scientific freedom."

The warning is often heard that science is leading the world headlong to disaster and that only the so-called humanities can bring back the moral strength and the wisdom needed for peace and safety. In Dale's opinion this imputation must be firmly contested, since science has a contribution of its own to make to cultural and moral equipment—not less than that made by any body of knowledge, art, or educational discipline. "It is not without significance that, whereas history, literature, art, and even religion, all have national character and local attachments, science alone of man's major intellectual interests has no frontiers and no national varieties; that science, like peace, is one and indivisible."

MR. WILLIAM GILLIATT has been re-elected president of the Royal College of Obstetricians and Gynæcologists.

MR. J. M. K. HAWTON has been appointed a deputy secretary to the Ministry of Health following the appointment of Sir Arthur Rucker to urgent duties with the preparatory commission to the International Refugee Organisation.

ON July 4 it was announced that the Emergency Bed Service would receive calls from the South of England for patients requiring streptomycin treatment for tuberculous meningitis and miliary tuberculosis. During the month of July, 18 applications were made on behalf of patients with tuberculous meningitis and 5 for miliary tuberculosis. All but 6 were admitted.

THE CARE OF BURNED PEOPLE

A PLEA FOR A NEW POLICY

LEONARD COLEBROOK
M.B. Lond., F.R.C.O.G., F.R.S.
ECTOR OF MEDICAL RESEARCH COUNCIL'S BURNS UNIT,
ACCIDENT HOSPITAL, BIRMINGHAM

IE war has brought great changes in the outlook
ourned people. The 30% burn or scald is no longer
ntence of death: patients, even children, with a
burn or more may now recover. Deep burns
no longer become septic, and therefore do not need
nent re-dressing. With sepsis controlled and skin-
ting done early (sometimes on the first day), healing
uch more rapid, and most of the pain that was
ciated with burns in the past has gone; and with
e bad contractures which so often meant crippling
disfigurement for life.

this article I shall not present detailed evidence
support of the above statement, nor indicate all
e whose work has contributed to these changes, in
country and in America. We have produced some
he evidence from the M.R.C. unit [1–3]—and more
be forthcoming. It may suffice to mention here
or two facts from our own recent experience. In
Birmingham Accident Hospital, where separate
ds are set aside for burns and scalds (35 beds), and
e than 200 cases are treated as inpatients each year,
re have been, during the past twelve months,
y 2 instances of acute septic inflammation of a burn
of them a severe pyocyanea infection of both arms
hands, the other an almost trifling and transient
ptococcus infection which followed a grafting opera-
. In addition to this there have been three or
r intercurrent low-grade fevers—e.g., doubtful pneu-
nias in children which were not associated with any
nifest infection of their burns. We have not seen
irregular swinging temperatures that so commonly
ompanied a severe burn before the war, and the
eral condition of the patients has been remarkably
d. The death-rate among the 203 children, aged
2, treated during the last two years has been 3%,
compared with 32% among the 100 children of the
e age-group reported from the Toronto Children's
spital in 1923.[4] Among the 23 deaths from burns
scalds in our hospital during 1945 and 1946 there
s only 1 death from scalding in a child of the 0–12
-group (120 treated). Before the war such deaths
children accounted for over 30% of all the deaths
the Registrar-General's report.

It must, however, be freely admitted that these results
ve been obtained in exceptionally favourable circum-
nces. In addition to general supervision by Mr. W.
ssane, clinical director of the hospital, two whole-time
gical officers, a bacteriologist, a bacteriological tech-
ian, a biochemist, a secretary, and (besides the usual
rsing staff) a special nurse charged with the feeding
the severely burned cases have all been available
provide a 24-hour service capable of dealing with
sh cases without delay. No dressings have been done
the open wards, because of the risk of airborne infec-
n: all are carried out by a trained team in a special
essing-room with a dust-free and (almost) microbe-free
mosphere. More than 3000 dressings have been
rried out to date in this room. Very complete records
ggest that there has been no transfer of hæmolytic
reptococci, and only one of *Ps. pyocyanea*, from one patient to another during dressings. (For a report on added infections up till August, 1946, see Colebrook et al.[2])

Through the "shock" stage the care of the badly burned patients has been the immediate responsibility of the senior surgeon of the burns team, who will sometimes spend as much as 4–5 hours a day on a single case. And the skin-grafting operations have been performed by this same officer with the special skill born of almost daily practice. In addition, a plastic surgeon has been at hand, when required, to deal with the most difficult repair problems.

It will be admitted that these conditions are very different from those obtaining in most of our hospitals before the war (and presumably still obtaining in many), when the care of burns was usually the responsibility of a house-surgeon fully occupied with general surgical work, who often had had little or no previous experience of burns and usually dealt with only three or four of them during his term of office. Realising that the burns were almost sure to become septic, if severe, he was often only too glad to hand on his responsibility in large measure to the ward sister. The burns were admitted either to the ordinary surgical wards, which involved a considerable risk of cross-infections for the "clean" cases in these wards, or to a "septic block," which involved a greatly increased risk of infection for the burns themselves. All dressings were done in the open wards and almost all deep burns became infected. The frightful pain associated with their dressings is too well known to need emphasis.

It is abundantly clear now that these pre-war arrangements for burns did not give the patients the best chance. These distressing and difficult cases require a special set-up which all hospitals receiving only a few of them cannot be expected to provide.

RECOMMENDATIONS

Our experience in the burns unit leads me to conclude:

(1) That in all our larger towns and cities there should be centres in one or more general hospitals specially equipped and staffed to deal with these injuries; we should discontinue the practice of admitting them to all the hospitals.

(2) That all dressings of burns (and indeed also of all open wounds) should be carried out not in open wards but in specially ventilated dressing-rooms designed to avoid both airborne and contact infection. The ventilation plant can usually be fitted to existing buildings without great cost. In new buildings it would be a considerable economy to group all such dressing-stations and theatres centrally, to be served by a single ventilation system.

(3) That continuous and adequate bacteriological control is essential in running a burns centre, if infection is to be avoided and treatment effectively guided.

(4) That the teaching of students about burns should be done by the staff of such fully equipped burns centres who have experience of large numbers of these difficult cases.

(5) That it would be an economy of hospital beds in the cities, and also greatly to the advantage of the patients, particularly the children, if provision was made for their transfer to the near-by country for the later stages of healing. Such provision must allow for adequate treatment and medical supervision, as required—it must not be simply a convalescent home.

There can be no doubt that provision for burns and scalds on these lines would mean the saving of many lives (some 1200 people still die of these injuries each year in England and Wales); and an immense amount of suffering. The dressing of cases by a trained team in a dust-free atmosphere would also constitute another landmark in the progress of aseptic surgery.

With the planning and replanning of regional hospital facilities under the new Act surely the arrangements here suggested are worthy of immediate consideration?

PROGRESS IN MEDICINE

U.S. Army Symposium

THE latest developments in medicine and surgery were discussed in a three-day symposium held at the U.S. Army Medical Center, Washington, D.C., on June 3–5.

AMPUTATIONS AND PROSTHESES

Colonel AUGUST W. SPITTLER *said that artificial* hands that look like real hands and serve many of the same purposes are being developed by the army medical department. Hitherto the most useful artificial hand has been a steel hook; patients may become very skilful in its use but are always conscious of its appearance. With light plastic materials which look like flesh the problem of appearance now offers little difficulty. Activation of all the fingers and finger-joints has usually resulted in a unit too complex to be useful. Use of only the index and middle fingers to oppose the thumb appears to be the best combination, with the little and ring fingers for a stationary hook. Such a hand has been developed with multiple joints in the fingers in place of phalangeal segments; the index and little finger move towards the thumb in a converging motion. Most of the usual 30-lb. pull which can be produced by the shoulder shrug is delivered at the finger-tip. The ideal features of a hand—the capacity to hold an object 3¼ in. in diameter, resilient pads on the finger-tips, and positive closing control—are found in this hand. An artificial ankle has also been developed, with a spring mechanism which offers much of the advantage of a real ankle. Scores of suggestions for artificial limbs are being offered; but many are too complex.

PHYSIOLOGICAL EFFECTS OF WOUNDS

Dr. HENRY K. BEECHER described new principles in the treatment of the severely wounded, based on study of more than 1000 cases from the Cassino and Anzio battles early in 1944. Most severely wounded men do not suffer acute pain; three-quarters of those arriving at the most forward hospital, even though they had had no morphine for five hours or more, said they were not suffering enough to want anything done about it. On the other hand those with shock due to blood-loss nearly always complained of severe thirst. Patients with this condition were tided over, wherever possible, with plasma; but in Italy the plasma was found to be much less depleted than the red blood-cells—so much so that there must be some unknown reservoir of proteins in the body which is drawn upon in an emergency. It was shown that the quantity of blood and plasma needed for resuscitation can be reduced to about half of that called for by older and slower methods. At the same time delay in undertaking surgery because of shock can be cut by about two-thirds by whole-blood transfusions while the surgeon is at work. This economy of time and material will clearly be essential if military action ever takes place in inaccessible regions of the world, such as the Arctic or Antarctic. It will also be essential if large numbers of the population should ever be subjected to atomic radiation, with the consequent great blood-loss from serous surfaces.

TREATMENT OF LUNG ABSCESSES

Dr. BRIAN B. BLADES referred to the refinements in operative techniques, the improved anæsthesia, and the benefits of antibiotics which have made pulmonary resection a safe operation in the treatment of chronic pulmonary abscesses. The approximate mortality-rate in the surgical treatment of pulmonary abscess in 1942 was 15·2%. At the present time operative mortality for excisional surgery *in chronic pulmonary abscess* is about 5%; moreover, the number of satisfactory cures has increased from approximately 57% in 1942 to more than 80% at the present time.

During the late war the incidence of acute pulmonary abscesses in members of the Armed Forces was low. It is not surprising that abscesses secondary to wounds of the chest were uncommon, for it has long been known that the lung has tremendous resistance to infections introduced by foreign bodies. It is of interest, that so few cases of acute fulminating p abscess were found in the millions of men who the Forces. This rarity of the acute abscess replacement by a more chronic, indolent type of *ary suppuration may be explained by two* factor the army men have good dental care; dental abscessed teeth, and so forth do not exist, or are remedied. Thus one of the chief ætiological eliminated. Secondly sulphonamide derivatives on penicillin were almost universally used in all pulmonary disease.

Since patients were not extremely ill there tendency to delay surgical intervention; and where the infection responded to antibiotic surgical intervention was avoided. Where tissue tion was so gross as to require operative tre lesions were apt to be multiple, involving an or even the entire lung. Extirpation of the tissue in these cases gave excellent results. E very early cases where the abscesses were well scribed and drainage was instituted promptly, results were unsatisfactory because of the of multiple abscesses and destruction of parenchyma.

Data accumulated during the war, and su experience in civilian hospitals, indicate that for monary abscesses of all varieties excisional nearly always the treatment of choice. The for emergency drainage of a pulmonary abscess in very early stages has been largely obviated by the of penicillin and other antibiotics.

TREATMENT OF MALARIA

Dr. ALF S. ALVING said that plasmoquine, th cures benign tertian malaria, is much too toxic for the field. Hundreds of related compounds were in the war; finally that now known as pentaquine *found to be only about half as toxic and yet of* curative value than plasmoquine. Tests indicate pentaquine will reduce the relapse-rate in severely subjects from 98% to 16%, while in moderate inf the rate can be reduced to 4%; its effectiveness greatest when it is given with quinine. It however, not a drug for self-medication, and patient must be admitted to hospital; in very infections several courses may be necessary. valuable drugs were developed, in addition to (mepacrine); these are the American '*Chloroquin* and the British 'Paludrine.'

RESEARCH IN VIRUS DISEASES

Dr. JOSEPH E. SMADEL *described the isolation of* virus causing encephalomyocarditis. This virus a rapidly fatal disease, with a characteristic pattern mice, hamsters, cotton-rats, and monkeys; and a fatal fever in guineapigs and rabbits. In fatal case attacks the *heart-muscle and brain.* There was doubt whether encephalomyocarditis actually was disease of man, but it now appears that some of those the Pacific zone who had the so-called three-day f may have been suffering from encephalomyocard there was, however, *no involvement of the heart* brain, and the disease may have occurred only as complication of some other malady. The other new virus disease, which also does not appear serious is Fort Bragg fever. This is characterised by a fever and a rash, chiefly on the front of the leg The virus has been isolated; it appears to be extremely delicate organism, rapidly inactivated at low temperatures.

The discovery of a chemical substance effective against *viruses—especially the virus of influenza*—is one of major goals of present medical research. Some pro has been made in this direction; one drug which se to inhibit temporarily the growth of the influenza vi is closely related to mepacrine, but it appears to no practical value at present. Rockefeller Inst workers have lately reported that biological substan such as apple pectin and certain blood substances, an inhibitory effect on this virus.

THE PRISONS

k of staff has hit the prisons hard in recent years.
945 report of the commissioners and directors,[1]
has only just appeared, speaks of the handicap
s been to the progress of all schemes for the better
g, grouping, and educating of prisoners. Never-
, something was being done, and no doubt the
8 months have seen more rapid advances.

effects of staff shortage have been intensified by
ses in the numbers of prisoners. Thus the daily
ge population in 1945 was 14.708, the highest
since 1914–15, and the figure for 1946 was expected,
time when the report was prepared, to be some
).

most striking increase was in the number of committals
stal, where the daily average population for lads rose
1752 in 1942, to 2406 in 1945, and in the first nine
s of 1946 to over 3000. It is perhaps worth noting that
gure in the middle war years was lower than the figure
for 1938. Committals of girls show no such interim
they rose from 131 in 1938 to 234 in 1942, and 372 in
in the early months of 1946, however, there was a
wards the 1942 level.

e commissioners note that " so long as young persons
21 are sent to prison they will continue to make
est arrangements possible for their training, but
nothing they can do within the limitations of a
n can be regarded as satisfactory." This is frank
gh, and it is to the credit of the commissioners that
have not given in to the manifest difficulties of the
ion.

much physical training and evening education are given
rcumstances allow. Young lads with sentences of more
three months are segregated from the older convicts in
entres. They live in separate wings and work in separate
s, where a better class of industry is provided; they
iate at meals and in the evening, and the keynote of the
ing is liveliness. They are, the report says, given hard
interesting work, sharp but not repressive discipline.
girls are fewer and the physical limitations of their
ns greater, the same standard of training for girls is only
eved in Holloway.

n attempt to keep the younger men among the
lt prisoners away from the older ones has not proved
essful. The aim was to give special training to men
veen 21 and 26 (or in special cases up to 30) who were
eligible for the " star " class. This experiment had
e dropped during the war, and the commissioners
e decided not to continue it. It seems that young
of this age and character have a bad effect on one
ther, and they are " much better among older men
are not impressed by them and have a steadying
uence." Men are taken on agricultural working
ties, and during the year similar working parties were
nged for women, and proved successful. Women
e also been used by some of the London hospitals
lomestic workers. Star prisoners continue to do well:
7% of those released from Wakefield Prison training
tre are never reconvicted. The proportion of dis-
rged prisoners reconvicted after a first sentence is
ewise extremely low: of 126,191 serving first sentences
ween 1930 and 1942, 82% had not been reconvicted
to the end of 1944. Moreover, nearly half the
idivists from Dartmoor are satisfactory after an
erage of 2½ years of liberty.

At Durham an interesting educational experiment is being
ried out by the local education committee, which is treating
prison as an evening institute, and providing a full curri-
um of voluntary classes in subjects as widely varied as
ler-room practice, economics, technical drawing, and
dern problems, on the men's side, and mothercraft, house-
ld economy, cookery, music, and drawing, on the women's
le. This has proved so successful that it is now firmly
ablished and will be discussed more fully in the next report.

During the year under review the delays experienced
prison by boys waiting places in borstals were so great
at Dartmoor Prison had to be used temporarily as a borstal institution; and at the end of the year it was estimated that accommodation was needed for 1000 additional boys in training as well as a second reception and allocation centre. All these have been provided: a new reception centre for 150 and a new camp for 75 have been set up; three big country houses have been converted into borstals, and Feltham, which was used as a prison during the war, has become a borstal again. Whereas in 1945 some 600 boys were waiting anything up to five months for places in borstals, by December, 1946, only about 20 were waiting the next weekly escort to a reception centre for classification and allocation.

Agencies for the aftercare of prisoners continue to do good work.

The Discharged Prisoners' Aid Societies have been successful in finding employment for ex-prisoners, and the Central Association gives financial help to those who need it, and friendly guidance to ex-prisoners settling-down in ordinary life. During 1945 many men were released after serving court-martial sentences, and most of these were not criminals in any ordinary sense, their offences being against military discipline rather than against society. The association has made special efforts to help these. Of 1067 discharged prisoners dealt with by the association during 1945, 78 required no help, and 611 returned to the Services; help, maintenance, working clothes, or tools were given to 304, of whom 74 found their own employment and 230 had jobs found for them. Only 57 of those given maintenance and advice were unwilling to coöperate; 4 more were found to be unemployable, and 13 were certified by the prison authorities as needing institutional care.

Thanks to the help of the Fighting Services and Ministry of Labour, many thousands of discharged borstal boys were able to enter the Forces without carrying any stigma.

TRAINING IN CLINICAL-PATHOLOGY

" Clinical pathology includes the application of laboratory methods of all kinds—bacteriological, biochemical, hæmatological, and histological—to clinical problems. Part of the work of the clinical pathologist is concerned in diagnosis, but an increasingly large part related to the control of treatment of various disorders whose progress can be most accurately assessed by laboratory methods. A clinical pathologist is a consultant who can advise on the diagnosis and treatment of all such forms of illness as fall within his province, for example, infections, blood diseases, and metabolic abnormalities."

THE subcommittee appointed last January by the Association of Clinical Pathologists, to consider the training and qualifications of a consultant in this specialty, hold that in view of its scope, as outlined above, the consultant should have a sound clinical training as well as wide experience in laboratory methods, and higher qualifications in medicine.

The subcommittee, consisting of Dr. E. N. Allott (chairman), Dr. S. C. Dyke, Dr. R. W. Fairbrother, Dr. J. G. Greenfield, and Dr. W. H. McMenemey, have just issued their report. There is already, they say, a shortage of trained clinical pathologists, while the demand for them, under the National Health Service Act, is bound to grow. Entrants to this specialty, they suggest, should not be recognised as consultants until they have had five years (or four years if they hold a first-class or second-class honours degree in science, or a research degree, such as doctor of philosophy) of post-registration experience, and hold a higher medical qualification. Their training should be in three parts: one year of further clinical experience, one year in a university department, and two years in a department of clinical pathology. The remaining year should be spent in getting further knowledge and experience of any part of the subject in which the candidate is specially interested.

In the year of post-registration clinical training, six months would be spent as a house-physician in general medical wards, and a further six months in other clinical (not necessarily medical) appointments. An appointment as resident pathologist—though valuable experience—should not count as part of the *clinical* year. The year in a university department should be spent early in training, so as to influence the whole of the candidate's subsequent work. He should be encouraged to take a diploma in either bacteriology or clinical pathology, but the subcommittee do not feel such a diploma to be essential, or that the year must necessarily be spent in the department of pathology: scientific training in any department—the chemistry or physiology laboratories, or the laboratories of a professorial clinical unit—would be equally valuable.

---

[1] Report of the Commissioners of Prisons and Directors of Convict Prisons for the Year 1945. Cmd. 7146. H.M. Stationery Office. Pp. 120. 2s.

The two years spent in the department of clinical pathology of a large general hospital, or a group laboratory serving several hospitals, should include periods of six months each in the study of hæmatology, bacteriology, chemistry, and morbid anatomy. The department should carry several senior pathologists: training in a one-pathologist laboratory is undesirable, and the subcommittee suggest that a special committee should be set up to approve laboratories as suitable places for training, and that only training in approved laboratories should be recognised. The candidate's higher medical qualification should be the degree of doctor of medicine, or membership of the Royal College of Physicians.

It is not possible to apply all the above criteria to all existing clinical pathologists, or even to some well advanced in their training, but the committee suggest that no-one should be recognised as a specialist in this field unless he has been registered five years and has had a minimum of four years' laboratory experience. They do not feel, however, that a register should be prepared for the specialty. Financial assistance in the form of scholarships and Government grants should, they think, be available to candidates, and a considerable number of senior appointments carrying an adequate salary should be created for the purpose of completing the training of future consultants.

Public Health

A HYGIENIC FORK

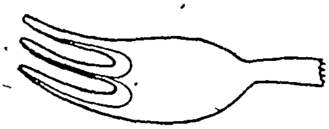
I. GORDON

M.D. Edin., M.R.C.P., D.P.H.

DEPUTY MEDICAL OFFICER OF HEALTH, ILFORD, ESSEX

THE average article of cutlery seems to have been expressly designed to make cleaning difficult by providing grooves and niches from which dirt cannot easily be removed. Witness the elaborate and unnecessary grooves on the knife at the junction of blade and handle and, above all, in the spaces between the prongs of the ordinary fork.

The shape of the fork does not seem to have varied for hundreds of years, and cleansing between the prongs, especially at their bases, has been made as difficult as possible by poor design. It is strange that so much fuss is made over the occasional cracked cup, when every fork is even more a trap for germs. To illustrate the problem a fork was examined at each of 100 consecutive visits to restaurants, mainly patronised by the middle class, in inner and outer London. Only 21 forks could be called macroscopically clean. Visible foreign matter, ranging from faint films of grease to lipstick, polishing powder, and pieces of vegetable, was seen in 79 between the prongs.



To design a fork that can easily be cleaned is simple. Some of the features of the fork described here will be familiar to all, but one feature, the bevelling, is, so far as I know, original. To decrease the area to be cleaned there should be three prongs instead of four, and they should be half their present length. To make cleaning easier the adjoining sides of each pair of prongs are bevelled (see figure) on their convex surfaces.

It is obvious that, if the back and front of this fork are rubbed with a cloth, there is no surface or crevice that is inaccessible, and all gross dirt can be removed. A fork so cleaned is not rendered sterile, and any however ill-designed, can be sterilised by suitable of heat and detergents; nevertheless, until the arrives, if ever it does, when sterilised utensils are rule in home and restaurant, there is no need for put up with gross dirt in our forks due to our archaic, and ineffective design.

I have to thank Mr. H. Bradley, of the public department, Ilford, for making me a trial fork to specifications.

The Ineducable Child

A child reported to the local authority under Mental Deficiency Acts as ineducable is autom deprived of the right to education in special school class; yet, as a correspondent points out (p 24 child who promised to be ineducable at the age may present a much more hopeful picture at the 5: indeed he may then, or earlier, be suitable for education. Under the old legislation he could been transferred at once from an institution for and imbeciles to a special school for the feeble- but the provisions of the Education Act, 1944, such easy transfer nowadays impossible. That Ministry of Education is aware of the difficulty ap from its circular (no. 146) on Educationally Subn Children. After examining a child, an "appro medical officer" advises the local education aut on the type of special educational treatment n or, if he considers the child ineducable, he ad that it should be reported under the Mental Defic Acts.

Yet even the best doctor, when dealing with the v young, cannot be certain whether a child is really in able; and to meet this difficulty the Ministry has viously asked that education authorities should "ex great care" about reporting children under the A Despite this, there have—almost inevitably—been of children mistakenly reported. The Minister of Ed tion and the Board of Control therefore suggest in the case of children between 2 and 5 local edu authorities should report only those whose "ineduca is obvious," and that others should be given a trial in ordinary or special school. Moreover, it would open to the local authority to deal with children the age of five who, although not reported, should in opinion be dealt with under the Mental Defic Acts." This seems to meet one of our correspondent difficulties, for it means that parents can be relie of a child who, without being of so low a grade as need "reporting," would yet benefit by a period a mental-deficiency institution. Provided that order made under the Mental Deficiency Acts discharged, such an "unreported" child can be t ferred, at the age of 5 or after, to the care of education authority.

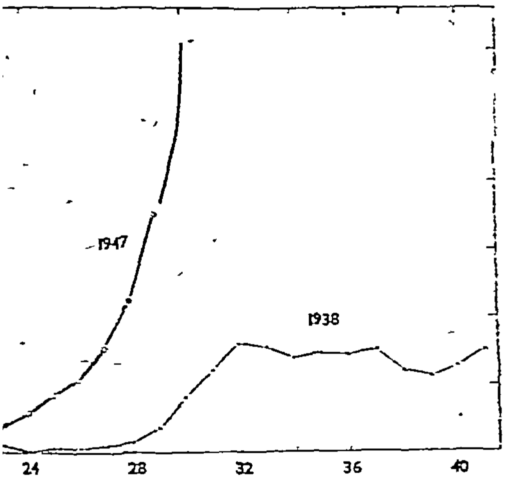
Poliomyelitis

Notifications of poliomyelitis in England and W during the week ended July 26 numbered 302 com with 177 in the previous week. As the accompan chart shows, the gradient in the curve of incidence become somewhat steeper, and there is nothing suggest that the peak has been reached. On the contra the number of new outbreaks brought to the notice the Ministry of Health during the past week suggest a further rise is to be expected.

Counties in which notifications reached double fi during the week ended July 26 were: London Durham 20, Essex 13, Lancashire 17, Middlesex Surrey 15, Warwickshire 20, and West Riding of Y shire 52. Removals to infectious-disease hospitals the London area have decreased slightly: in the se days up to July 28 they numbered 70, and in the se days up to August 4, 61. The incidence in Lewis the metropolitan borough so far most affected, ap to be abating.

Earlier reports suggested an unusual proportion cases with marked meningeal irritation at onset, but th the more usual and milder clinical types, in w paralysis appears without striking prodromata, are le found more commonly, and the steep gradient in ded July 26 may be an expression of late s and delayed notification.

ugh cases are widely scattered over England and the incidence is by no means even, and large f the country are not yet involved. The need npt diagnosis and notification of first cases in eas will be apparent. In localities where the is in the first or second generation particular n must be paid to close contacts, more especially develop a minor indisposition insufficient to their movements. At the start of an outbreak is is probably confined to the patient and his timate companions. The mechanism of direct s still uncertain; but of late years it has become ngly evident that spread is usually from person



son following fairly close contact with a previous f abortive or paralytic disease during a relatively period of infectivity which begins a few days any sign of illness. When infectivity appears to its height the virus is present in the oropharyngeal ions; it may also be present in the bowel at the time, but the most potent source of infection ost certainly the mouths of patients during the ralytic phase or during a subclinical attack.

POLIOENCEPHALITIS

tifications of polioencephalitis for the week ended 26 totalled 34. The figures for the first three weeks ly were 9, 16, and 16, compared with an average of 1–2 during the corresponding weeks in 1938–46. notifications of polioencephalitis began to increase s suggested by some that there might be a prevalence infection of the central nervous system other than nyelitis; but it is now certain that the bulk of ncephalitis notifications relate to infections with oliomyelitis virus. In past years the ratio between ions of poliomyelitis and polioencephalitis has not d much, usually being between 6 and 9 to 1; this s experience is not remarkably different.

Infectious Disease in England and Wales

WEEK ENDED JULY 26

ifications.—Smallpox, 0; scarlet fever, 987; ping-cough, 1924; diphtheria, 174; paratyphoid, typhoid, 8; measles (excluding rubella), 7644; monia (primary or influenzal), 311; cerebrospinal , 31; poliomyelitis, 302; polioencephalitis, 34; phalitis lethargica, 3; dysentery, 61; puerperal xia, 133; ophthalmia neonatorum, 55. No case of ra, plague, or typhus was notified during the week.

aths.—In 126 great towns there were no deaths from ic fever or scarlet fever, 2 (0) from diphtheria, from measles, 5 (2) from whooping-cough, 61 (4) from hœa and enteritis under two years, and 7 (0) from enza. The figures in parentheses are those for lon itself.

e number of stillbirths notified during the week 248 (corresponding to a rate of 26 per thousand on.

In England Now

A Running Commentary by Peripatetic Correspondents

FOR close on a quarter of a century, man and boy so to speak, I have been an F.R.C.P. Yet it was only last week that for the first time I had occasion to take a taxi to the College. "Where is that, sir?" asked the driver, although we were only a short half mile from Pall Mall East. "I've been a driver for twenty years," he continued, "but this is the first time I've been asked to go there. Of course, I've driven often enough to the College of Surgeons"

The somewhat gratuitous "of course" started the inevitable train of thought. Perchance, I reflected, the explanation is simply geographical. The R.C.S., ensconced in Lincoln's Inn Fields, is remote from tubes and bus routes, while we are more conveniently situated. But to be honest I admit this is mere casuistry. Only too obvious is the contrast between the practitioners of the two branches of the profession. We impecunious physicians are not in the taxi class.

* * *

The Princess, the Woodcutter's Son, and the Rhesus Monkey. (A tale told to an anxious parent who, on reaching the conclusion that her only daughter was Rh-negative, asked her doctor whether she should investigate the rhesus factor of any eventual suitor.)

ONCE upon a time there lived a king and queen who had but one child, a daughter, all the rest having been miscarriages. Such was the enlightened state of the times in which they lived that the court physicians were able to tell the queen that this was because she was Rh-negative and her husband, the king, was Rh-positive. They were of the opinion that this must have been a gift from a malevolent fairy at her christening, but with all their knowledge they could find no way of breaking the spell. On questioning her parents the queen learned that there had been present at her christening a queerly dressed old lady with a face like a monkey, who had been heard muttering something which might conceivably have been a spell. Instead of the usual "Hocus, pocus, magnum locus" ritual, it sounded like "Rhesus, squeeze us, taunt and tease us," and nobody could see any sense in that, so they thought that the old lady was mad and didn't like to cross her, even though she lingered an inordinately long time at the cradle and was messing about with needles and lengths of rubber tubing and flasks of red liquid, so that it would almost have seemed as if she were giving the child a blood-transfusion if it hadn't been such a ridiculous idea to think that she *would* in front of all those people. Everyone there was so well bred that they pretended not to notice, and when she'd finished the king gave her a glass of his second-best champagne as he thought she wouldn't know the difference, and after giving him a dirty look she went away.

The queen was a little upset at hearing the story, but, realising that there was no remedy for it, concentrated her care and affection on her daughter, the Princess Dewdrop, and persuaded the king that great care must be taken when the time came for the princess to be betrothed.

When the princess came of age, proclamations were issued and heralds went round inviting applications for her hand. Six handsome (according to themselves) princes turned up at the palace on the appointed morning and along with them came a lusty youth of great strength and beauty who was the third son of a humble woodcutter. His two elder brothers had jeered at him for setting out on such a quest but he was a good-tempered boy who always made a point of being polite to hideous old women and rescuing toads in distress, and he knew that such traits in the third sons of humble woodcutters invariably led them on to fortune. He therefore paid no attention to his brothers' gibes and went on his way with his heart full of hope.

Sure enough, he looked so beautiful, standing beside the six other suitors in his woodman's clothes, with the glow of health on his cheeks and the sun shining on his brown curls, that the princess fell in love with him at once. The six princes, in spite of their silken and velvet garments, were rather a pasty-faced lot, but the princess was a sensible girl and realised that there were many things to be taken into consideration when choosing a husband. So she remained silent while her father described the various tests and trials which the candidates must undergo to qualify for her hand.

For five days the suitors were busily engaged in slaying dragons, scaling glass mountains, rescuing damsels in distress, &c., &c. Each day one of the seven suitors was knocked out in the contest, until on the sixth day there only remained in the running the woodcutter's son, whose name was Hilarion, and the Prince of the Sunset Isles, who was quite the ugliest and most pasty-faced of the lot.

For the sixth and final test the candidates were ushered into the presence of the court physicians, the two chief of whom advanced toward the two young men carrying wide-bore needles and glass tubes. With these they took samples of blood for rhesus tests, without so much as a by-your-leave or even saying "Just a prick." The sight of his own blood dripping into a test-tube caused the Prince of the Sunset Isles to swoon away, and the downright impertinence of the whole proceeding so annoyed Hilarion that he let forth a long string of curses that he had picked up in the woods from angry squirrels who objected to having their favourite trees cut down. When it was explained that this was the most important test of all, which would decide without a doubt who would marry the princess, the Prince of the Sunset Isles ceased swooning because he thought it was a test to see whose blood was bluer, and he knew his was; and Hilarion stopped cursing because he thought it was a W.R. and he knew his was negative.

The princess's excitement when they brought her the results was somewhat dashed on discovering that the Prince of the Sunset Isles was group O, Rh-negative, whereas Hilarion was group A, Rh-positive, she herself being group B, Rh-negative. She was, as has already been pointed out, a sensible girl, so she married the Prince of the Sunset Isles, whom she hated, and they lived unhappily ever after; the prince turned out to be impotent, so no children blessed the union.

Hilarion went back to the woodcutter's cottage, where his brothers jeered at him more than ever. Goaded by their taunts, he was caught on the rebound and married in indecent haste one Maribel, the daughter of the village blacksmith. They lived happily ever after, even though Maribel was later found to be every bit as Rh-negative as the Princess Dewdrop. They had two daughters and a son whose life was saved by blood-transfusions, and the children lived as brilliant examples of the art of How to Be Happy Though Negative. Which only goes to show how wonderful science is.

* * *

You do meet some funny types with annoying habits in higher examinations. The chap next to me the other day waggled one foot steadily up and down, without stopping, throughout the whole twelve hours of written papers. I got to loathe the sight of that foot. If I'd had a gun I should have been very inclined to fire it. Another chewed and rustled paper incessantly, and yet another would keep asking to be "excused" every hour. Every time he got up he knocked my desk back and spoilt a page of writing, but he never apologised.

Examiners may have their trials, but so have candidates.

* * *

Here is an extract from a letter from an Arab who calls on doctors in Palestine on behalf of a drug firm:

"Last week I called on a French doctor who has adopted the Moslem faith. It was the most unconvenient visit I have ever made. His behaviour was so dreadful. When I showed him our new syphilis remedy he asked if it is painful, and I told him to try it and see. I meant to try it on one of his patients or more. Immediately he started to sterilise the water and prepare the syringe! I asked him, with astonishment, what does he want to do? and he asked me to take off my trousers and lie on the couch. He insisted on trying the remedy on me, to see if it is painful or not. He was behaving seriously! How to escape from this mad doctor, I was thinking deeply. Finally, after a long argument, he made me agree with him that it is painful, otherwise he has to try it on me."

Letters to the Editor

PROGNOSIS IN ERYTHROBLASTOSIS FŒT

SIR,—In connexion with your interesting anno of April 5, it may be of interest to your readers to of our experiences with exchange transfusion.

Our first experiments with the procedure were don 1944, and, while we succeeded in accomplishing a replacement of blood, the method was tedious difficult because coagulation hampered the withd of the infant's blood. In the absence of a satisf rationale for the procedure and in view of the tec difficulties, we abandoned the method tem When in 1946 we worked out a satisfactory rationale the use of exchange transfusion and devised a tec that was safe and simple to perform we began to the method as a routine for the treatment of e blastosis.

The rationale for the procedure depends on the f the union of the maternal Rh antibodies with the erythrocytes may produce either one or both of effects—hæmolysis or clumping. In cases when hæmolysis takes place, a hæmolytic anæmia results is readily combated by the simple transfusion of negative blood, and infants treated in this way completely and exhibit no sequelæ of the disease. intravascular clumping occurs, due either to agglut or to conglutination, the circulation to vital particularly the liver and the brain, is compromised the infant usually dies. The occasional child survives the early severe stages of the disease exhibits the sequelæ of severe cerebral and h damage. Obviously these infants will not be be by simple transfusion, since plugging of the vessels clumps of erythrocytes produces irreversible changes. For reasons explained in our publications the subject, intravascular clumping rarely takes in utero. It usually occurs after birth, and in fact to be initiated by the birth of the infant. At birth the infant's cells are merely coated by the mat antibodies and not yet clumped. Accordingly, if infant's blood is immediately withdrawn and re by inagglutinable Rh-negative cells, it should be to avoid the disease. The recent development of methods of detecting Rh sensitisation, and the perf of Rh-Hr typing, have made it possible to predict appearance of the disease in the unborn infant, and prepare blood ahead of time, so that the infant can treated within minutes after it has drawn its first b

With the aid of suitable safe quantities of he using the saphenous vein for infusion and the r artery for bleeding, a very satisfactory exchange fusion can be carried out in 75 minutes. Since the bl ing and the infusion are done simultaneously, some of infused blood will be lost in the bleeding process that an exchange of 100% is impossible. Calculatio shows that when an amount of blood equal to the bl volume of the infant is simultaneously infused removed, a 65% replacement is accomplished, with double this amount 85–90% of the blood exchanged. In our procedure we routinely use 500 c an amount equal to twice the blood volume of average infant. The immensity of the procedure is appreciated until it is pointed out that this amount equivalent to injecting and withdrawing 10,000 c. of blood in an adult. Parenthetically it might mentioned that other workers in attempting to ac plish the same result by somewhat different techniq find themselves so limited by the methods used that t are satisfied to terminate the procedure when as li as 200 c.cm. of blood have been exchanged.

Thus the two objections to the use of exchange t fusion—the absence of rationale and the difficulty of technique—have been removed. A third objection now been raised, as mentioned in your annotat This is that the infants who may be saved only sur for the worse fate of mental deficiency due to h damage. That this objection is not a valid one is sh by our personal experience with 19 cases of pr erythroblastosis fœtalis treated by exchange t fusion and studied with great care thereafter. Of th 19 infants only 2 died. Each had d a sibling stillborn. The surviving 17 children have all ered completely and are entirely normal in their ical and mental development. Certainly this d justifies the procedure for routine use. It is safe, tive, and so simple to carry out that any transnist who has once witnessed it or merely read a led description can perform it without difficulty.

ALEXANDER S. WIENER
oklyn, N.Y., U.S.A. IRVING B. WEXLER.

A RECORD LOW HÆMOGLOBIN?

R,—In their letter of June 7 Dr. Karani and Szekulesz reported the case of a patient with 12% ioglobin. Here lower figures than this are common. erty and illiteracy are the prime causes of the ailing undernourishment, and they also stand in way of patients seeking treatment at an early stage. uch varied conditions as sprue, tropical macrocytic mia, anæmia of pregnancy and lactation, deficiencies he vitamin-B group, ankylostomiasis, and chronic aria (in the last two the parasites aggravate the existing anæmia in an undernourished individual) meets with hæmoglobin levels of about 10%.

give below the history of one such case that came er my observation.

man, aged 38, consulted me early last June with a ory of weakness, dyspnœa on slight exertion, palpitation, ling and numbness of the lower extremities, poor appetite, ility to take spicy foods, and flatulence for the past six ths. He was extremely pale and emaciated; finger-nails tle and spoon-shaped; slight œdema of the dorsum of feet of the legs. Temp. 100°F. Tongue raw and fissured, illæ atrophied and smooth; stomatitis present. Liver spleen not palpable. Heart: hæmic murmur, best heard ulmonary area; bruit-de-diable over the jugulars. Pulse-e 114 per min.; blood-pressure 86/62 mm. Hg.

Blood: red cells 560,000 per c.mm.; Hb 11% (Sahli's le); white cells 4600 per c.mm. (polymorphs 64%, lymphoes 31%, eosinophils 4%, monocytes 1%). Motions: no found. Urine: nil abnormal.

No transfusion was possible in the out-of-the-way lage where the patient lives. He was put on a liver-n preparation, nicotinamide tablets (200 mg. a day), th digestive stimulants like 'Taka-Diastase' and nourish food. After a month he has improved symptomcally and objectively; he is able to take food and ves about more freely. On July 15 red cells totalled 00,000, and the hæmoglobin was 32%. The patient s been advised to follow the regimen for at least two nths more, but a month's medicine alone absorbs out three-quarters of his income, and naturally his nily suffers from undernourishment indirectly.

Kumbakonam, South India. R. VENKATARAMAN.

EFFECTS OF CANNABIS

SIR,—Adams[1] in 1942 described chemical, pharmacogical, and clinical experiments with marihuana, and ockings[2] has reported clinical work with cannabis eparations. We have recently had the opportunity administering 'Synhexyl,' a synthetic cannabis eparation, to ourselves and we thought it worth hile recording our personal experiences in view of is drug's possible application in psychiatry.

At first 20 mg. was taken and the sensations experienced ere pleasant but slight. One of us developed a slight ontal headache, but mostly there was a feeling of all being well with the world." Repetition of this dose roduced a sleepy feeling, and observers said that we oked tired and half drugged.

Later a further dose of 40 mg. was taken, and this roduced a marked effect: headache, apathy, increase pulse-rate, a tremendous increase in the sense of time d distance, marked analgesia, and some tendency to ugh foolishly. It was difficult to explain an intention r an action. Suddenly in the middle of a sentence a ord would be repeated again and again, until by a emendous effort the sentence was continued. For me time simple acts, such as putting a kettle on a gas ng and lighting the gas, were impossible for one of us; although what was needed was realised, concentration was too imperfect for the chain of actions to be completed.

Emotional apathy was pronounced, and in the face of another person's danger there was complete detachment—e.g., a small child running round a room holding a large jagged piece of glass in its mouth did not create a feeling of apprehension. There was a sense of muscular weakness, but there was no apparent diminution in muscular power. Movement was avoided because of the mental effort required.

After some hours a drowsy feeling set in, accompanied by a sense of drifting in space with the walls of the room receding and advancing. The effect of the drug did not wear off for about 36 hours; towards the end of this period there was some frequency of micturition.

Welwyn Garden City, Herts. FRED WRIGLEY.

TYPHOID-PARATYPHOID (Vi) VACCINE

SIR,—When I wrote my letter of March 29 I did not know of the exhaustive paper on the Preservation of Vi Antigen in T.A.B. vaccine by Surgeon Commander S. G. Rainsford published in the *Journal of Hygiene* (1942, 42, 297). Having now read it I regret my remark that "Rainsford tried higher concentrations and discarded the vaccine as unsuitable." The only explanation I can offer for the oversight is that the paper was published after the fall of Singapore in 1942, and during the occupation period I had no access to new medical literature. Even now we are unfortunately not in possession of the current and back issues of many journals, of which *Journal of Hygiene* is one.

Dept. of Bacteriology, College of Medicine, Singapore. N. K. SEN.

TAKE-UP OF VITAMIN SUPPLEMENTS

SIR,—The London Divisional Food Office area comprises 94 local authorities or food-office areas. I have noted for some time that the take-up figures of vitamin supplements for each area, which are periodically issued, remain fairly constant, and that from a cursory glance there appears to be, in general, a higher take-up in what might be termed the better-class areas which are also associated with lower infant-mortality rates.

By the kindness of the statistical branch of the Registrar-General's Office I have been furnished with infant-mortality rates for each of these districts for the year 1945, and the following table gives the mean percentages of the potential take-up of the issues of orange juice, cod-liver oil, and vitamin A and D tablets, grouped according to those areas where the infant-mortality rates for 1945 were under 30, 30–39, 40–49, and 50 and over:

VITAMIN SUPPLEMENTS: AVERAGE WEEKLY ISSUES AS PERCENTAGE OF POTENTIAL AND INFANT-MORTALITY RATES PER 1000 LIVE BIRTHS

Infant-mortality rates per 1000 live births 1945	No. of food-office areas	Mean % potential take-ups of—					
		Orange juice		Cod-liver oil		A & D tablets	
		Mean	Standard deviation	Mean	Standard deviation	Mean	Standard deviation
Under 30 ..	13	57	12	35	10	59	9
30–39 ..	44	56	18	32	7	60	10
40–49 ..	26	46	10	30	5	51	10
50 and over	11	44	11	25	7	41	8

It will be noted that there is an inverse association between the degree of take-up and the infant-mortality rate. The above table, of course, represents the information from one region only, and the trend shown in this will require supporting evidence from the rest of the country. The proportionate take-up of Ministry of Food vitamin supplements cannot yet be regarded as a reliable indicator of child health or social circumstances! Neither does it prove that an increase in the take-up of

---

1. Adams, R. *Bull. New York Acad. Med.* 1942, 18, 705.
2. Stockings, G. T. *Brit. med. J.* 1947, i, 918.

the supplements would of itself have an effect upon the infant-mortality rate, but it seems reasonable to assume that those social factors which affect the rate may also operate and affect the degree of take-up of the vitamin products. The low figures are all the more to be regretted since it would appear that the take-up is least *where the need is greatest, and since optimum feeding* of the expectant mother, including vitamin supplements, may have a favourable bearing on neonatal mortality at the very least. Special consideration of adverse local circumstances should therefore be given to those areas with low figures for distribution of vitamin supplements. Such factors may be psychological, educational, or connected with the location of or sessional times of the centres distributing vitamin supplements, and they should be carefully reviewed in the light of local circumstances by doctors, midwives, health visitors, and local food offices.

THE DENTAL HYGIENIST

SIR,—Your annotation of August 2 says that the New Zealand *dental assistants are permitted to practise* dentistry in the full sense of the word, the only condition being that they limit their activities to school-children and nominally work under supervision. This is rather misleading since they can only practise as civil servants; they only fill cavities not involving the pulp and only extract teeth with local anæsthesia. Teeth needing root-filling, crowning, &c., and difficult extractions or general anæsthetics are attended to by qualified dentists. Orthodontic and prosthetic treatment is also outside the nurse's sphere. Although many experienced nurses work without continuous supervision they are subject to frequent and irregular visits by the district principal dental officers who inspect their operative and educational work and demand a very high standard indeed.

You state that this is pure dilution and clearly *unacceptable in this country. It is difficult to see* why it is unacceptable here, when it has by its remarkable success earned the enthusiastic approval of the public and the dental profession in New Zealand. The Teviot Committee reported that, while they could not agree on the merits of such delegation, they agreed, except General Helliwell, that it should await the proof of a shortage of dentists to work a comprehensive dental scheme. The only reason they gave for this was that they wanted the coöperation of the profession. The arrears of dental work which, as you say, are so painfully conspicuous today, surely prove that something drastic of this sort is needed now. General Helliwell's minority report also expressed this view.

London, N.W.6. R. B. D. STOCKER.

VISITING THE SICK

SIR,—More visitors are needed today for public-assistance institutions and for long-stay patients in hospitals and infirmaries. Some of these people have no-one of their own to come and see them. Some of them are active enough to be able to go for a drive in a car, and car-owners could give great pleasure by taking one or two for a run with them when they are driving some distance. Shopping service, too, can be a great help to those who have pocket-money but are unable to reach the shops to spend it. Personal contacts made in this way can add a touch of colour to lives which are otherwise very colourless.

United Societies Club, S.W.7. OLIVE MATTHEWS.

LACTIC-ACID INJECTIONS OF JOINTS

SIR,—I read with interest the letter from Dr. Heald and Dr. Martin (July 19) on the results of treating arthritis by injections into the joints.

I have for the last year been carrying out this form of therapy at the Bermondsey borough-council health centre. In order to try to assess the severity of the arthritis and to judge which type of case is best suited for this treatment, in conjunction with the radiologist I have classified our cases of osteo-arthritis of the knee into three groups, as follows: (1) cases showing no X-ray changes of osteo-arthritis (though there may be early physical signs); (2) cases showing moderate sclerosis of the joint surfaces together with mild lipping; and (3) cases showing diminution of joint space, much lipping, or loose bodies. I have been injecting all three types but I have subdivided my cases into those in which injection tre is started after physiotherapy has failed to relieve and those where injection is given after X-ray ex but before any physiotherapy is given.

The number of cases treated by these standards i yet great, nor the duration of treatment long; during the year I have observed that in mod arthritis one injection followed by a fortnight of wave diathermy abolishes all pain, and the patient n a great improvement in the power of the joint.

In my earlier cases I used to inject into the knee 15 c.cm. of 1% acid *potassium-phosphate solutio* I found that this was accompanied by extreme pa the time of the injection and patients refused to h second injection. Now I anæsthetise the skin and syn membrane by a preliminary injection of 2% proc and to the 15 c.cm. of phosphate solution I add 5 c.c the 2% procaine, making an injection of 20 c.cm. I find that in this way no pain is caused at the ti injection or afterwards, and patients are quite willi have further injections; several have asked for a re In some cases a tremendous reaction has occurred. needed three aspirations of fluid and immobilisati plaster for a fortnight; but when the reaction had p off the man was discharged from my clinic extre pleased with his knee, regarding the reaction as p the treatment.

Only *occasionally have I given a second* injec and my impression is that one injection follow diathermy for a fortnight produces an improvement could be achieved only after three or four mont physiotherapy alone.

I have ascertained the pH values of the synovial in several joints which had fluid in them before injection; but I have found that after injecti has been difficult to get any further fluid in to establish its pH in the week or so after inje If the pH was altered at the time of the injection would expect it to be back at its old value within days and that the pain would return; but the lasts a long time.

The fact that injection in early cases gives the results suggests that the phosphate solution acts o synovial membrane or the fluid acidity; where relief was obtained in cases showing eburnation sclerosis one might consider that it acted on the raw areas by relief of friction or local thrombosis. A moment the mechanism of relief can only be conject

THE "INEDUCABLE CHILD"

SIR,—The new Education Act has been in oper for three years. It still contains, however, at leas striking defect which should be remedied at the ea possible opportunity. In *section 116 of the* Act listed those children who are exempted from educat provision by the education authority, and this includes all children who have been found incapab receiving education at school. The education auth may so ascertain a child at the age of two.

Even in the most skilled hands intelligence test fallible in children over the age of five; with you children they are little better than a gamble introduce into law relating to children of the age o such a static concept as that of permanent ineduca *was entirely* unwarrantable *either on scientific* or hu tarian grounds. The practical effect has been medical officers charged with the task of ascertain are often unwilling to issue a certificate of ineduca although quite clearly the child under consider may be in need of institutional care and unmanag at home. *If the law* were altered so as to exclude normal educational provision *only* those who are *time* considered ineducable, it would then caus misgivings to the ascertaining officer: he would that the child's prospects were not permanently imp

The effect on children who have already been with under the Act at an early age is serious. A con able number between the ages of two and five have been certified as ineducable since the Act came into f in one institution alone a review showed that o dozen children, on reaching the a five, ha *intelligence* quotient of over 50% *be reg* as educable in a school for ubn lren. Before the introduction of the Act these lren would have automatically been sent to a special ol of this type, but now they are considered per- ently ineducable.

literal interpretation of the Act may thus be used n excuse by the education authority not to face the of providing additional school facilities (residential otherwise) for such children. Moreover, many mothers be saddled with young unmanageable children who it benefit from a period of residence in a special tution, but who are unable to do so because no onsible doctor will sign a document permanently iving them, at the age of two, of the right to any 1 of education.

Mary Cray, Kent. BRIAN H. KIRMAN.

* This subject is discussed in our Public Health mn.—ED. L.

RED SQUILL

R,—Your annotation on How to Poison Rats ne 21) states that "red squill is of unreliable quality, n ineffective, and extremely inhumane." This gests that you are unaware of the existence of & O. (1943) no. 680—the Infestation Order, 1943— ch makes it illegal for any company or person to sell squill raticides unless they are licensed by, or receive norisation from, the Infestation Division of the istry of Food. The division requires that the red ll used for rodent control shall be biologically tested conform to a definite standard specification.

our statement, if accepted, would be damaging to reputation of a product which has given good service raticide.

RECORDS

IR,—Dr. Donnison's letter of August 2 raises the ole question of the fuller recognition and use of listics in the field of medicine. Nowhere is this more portant than in regard to the social and preventive ects of tuberculosis. For this reason, the keeping of urate statistical records should be part of the day-to- routine of every tuberculosis dispensary or chest clinic.

was particularly interested in Dr. Donnison's perience with the "Cope-Chat" Paramount Sorting stem because I introduced this method here last year l already find it invaluable in various ways. Firstly, quarterly return to the Ministry of Health is easily, urately, and quickly completed. Secondly, the rces of cases referred to the tuberculosis officer are dily analysed (i.e., private doctors, mass radiography, itacts, hospitals, &c.) and it is easy to assess which up are providing the most satisfactory "yield" of es. Thirdly, other variables (e.g., sex, age, occupa- n, stage of disease) can be readily correlated, and one n see more clearly which anti-tuberculosis measures uld be further extended, and which do not repay the ort expended on them.

Now, although I find the Cope-Chat system perfectly isfactory for sorting the index cards dealing with berculosis in a county borough with a population of 0,000, the system has two important limitations. rstly, it is not very easy to sort a pack of more than 0 cards at one time, and secondly the sorted cards re then to be hand-counted. Therefore, if one is ting up a statistical system to handle tens of thousands cases, or more, it may become more economical to e one of the more complicated statistical machines, me of which, besides sorting and counting the cards tomatically, also incorporate a device to eliminate ror in punching the index cards.

Last year the Tuberculosis Association approached e Joint Tuberculosis Council with a view to setting up bureau of statistics to deal with tuberculosis problems, any of which are susceptible of solution by proper atistical investigation. It is to be hoped that the new gional organisations will set up statistical bureaux to ake available much valuable information for the logical id economical development and coördination of hospital d administrative schemes in the future. quite apart om the value such records would offer for research.

W. H. TATTERSALL
Tuberculosis Officer, County Borough of Reading.

Parliament

ON THE FLOOR OF THE HOUSE

THE end of this part of the session will come as a welcome relief. Nor has it been only fatigue. Gossip suggests that the morbidity-rate among M.P.'s has been fairly high. The acceleration in the conduct of Parliamentary business is illustrated by the passage of the S.R.O. (statutory rule and order) dealing with superannuation and pension arrangements for the National Health Service. When a comparable scheme for the Civil Service was introduced into the House a number of years ago it took six months to get it through. The present S.R.O., which is more complicated, took only two hours—and that after 10 P.M. of an ordinary working day of Parliament.

There were disappointments last week about Mr. Marshall's proposal for immediate aid to Europe and about the Anglo-Soviet trade talks in Moscow. The United States Congress has adjourned without anything definite being achieved, and any U.S. plan must now wait for January next. The Anglo-Soviet talks were successful on most points except the method of repayment by Russia, and it is possible that the arrangements will be satisfactorily concluded during the summer. Meanwhile the Dutch-Indonesian flare-up, threatening an area of vast food-supply, is an example of the reasons why world food conditions do not improve more rapidly.

The Regular Army of the future will have to be larger than was contemplated, and it is hoped to recruit a considerable number of short-service medical officers in the immediate future. The question of the relation of these medical officers to the National Health Service is one of great importance. If an arrangement for "interchangeability" as regards pension and superannuation schemes can be arranged, the path of recruitment will be smoothed.

The dollar loan this country obtained from the U.S.A. and Canada will be virtually expended by November. Clearly we cannot put ourselves in the power of the United States and must depend on our own resources more than ever before. The need for cuts in imports, including everything except basically necessary foods, and the need for increasing our own food-production, is as great now as it was in 1940. The American loan has given us breathing-space, and we have reached an unprecedentedly high level of exports. But still more is needed and still more will be obtained.

MEDICUS, M.P.

End of the Temporary Register

The purpose of the Medical Practitioners and Pharmacists Bill, introduced in the House of Commons last Monday by the Minister of Health, is to dispose finally of the war-time problems associated with the registration of doctors possessing only qualifications obtained abroad. The Bill also deals with the question of pharmacists with foreign or Colonial qualifications.

Under the Bill the General Medical Council is empowered to grant permanent registration to three classes of doctors holding Colonial or foreign qualifications:

1. Doctors whose temporary registration under Defence Regulation 32B or under the Polish Resettlement Act will come to an end on Dec. 31, 1947. These doctors, notwithstanding the expiration of these regulations, are in any case to remain temporarily registered for 6 months from the passing of the new Act, during which time they may apply for permanent registration. Permanent registration will be conditional on the General Medical Council being satisfied that the doctor has rendered satisfactory service in a medical capacity during the period of temporary registration.

2. Doctors who have served in a medical capacity in any of the British Armed Forces (including the Dominion Forces, Indian Forces, and Burma Forces), and who are resident in the United Kingdom. Here, too, the applicant must provide evidence of satisfactory service; and he must apply within 12 months of the passing of the Act.

3. Doctors who have been permitted to enter the United Kingdom through circumstances attributable to war,

> *Permanent registration will here depend on the candidate holding some recognised Colonial or foreign diploma, or a qualification of the Polish School of Medicine at the University of Edinburgh; on his being of good character; and on his having been selected for employment in a hospital or other institution or service approved by the Minister of Health or the Secretary of State for Scotland. He must apply within 12 months of the passing of the Act; and for 6–18 months registration will be provisional only.*

Any doctor whose application for registration is rejected may appeal to the Privy Council.

For pharmacists the Bill formulates a general change in the law; the powers of the Pharmaceutical Society to make by-laws for the registration of Colonial pharmacists are extended to include those with foreign qualifications. The society is to decide what examination, if any, should be taken by the applicant.

FROM THE PRESS GALLERY

Housing

In the House of Commons on July 28 Mr. D. O. WALKER-SMITH described the Minister of Health's *record on housing as a ghastly failure.* Where were the new houses? There were under 90,000 by the end of May, instead of the Coalition target of 220,000. Generally speaking, local authorities and the building industry were doing their best, but their best was conditional on the planning and policy of the Minister. The supply of building materials was clogged by complex priority licensing schemes and by the subordination of the industry to bureaucratic requirements. Costs were rising and the situation was completely out of hand. The Minister should force Government departments and large local authorities to disgorge their big reserves of materials. He should also press for an incentive scheme of payment by results in the building industry.

Lady MEGAN LLOYD GEORGE said that the limited resources ought not to be dissipated by starting new houses all over the country; there should be concentration on getting as many houses as possible ready for occupation before the winter. The need for rural houses was critical if we were to increase food-production. Something like 100,000 new permanent workers were needed on the land. Where were they to live?

Mr. A. BEVAN said the main aims of the Government's housing policy were to build as many permanent houses as quickly as possible, and to see that houses were built for those in greatest need. The fact that they had provided in less than two years more than 250,000 houses, in addition to war-damage repairs, was not due to any administrative superiority that this Government possessed over that of 1918, but to the superiority of the Socialist principle over the Tory principle. During the last two years the Government had denied the building industry the right to build luxury buildings while the people needed houses. Account must be taken of the temporary housing programme, because in many cases it used up as much labour and materials as permanent houses. There had been complaints about the four-to-one ratio, but if the Government had to accept a constriction in the overall housing possibilities, houses built for sale would be almost entirely excluded. The houses now being built, said Mr. Bevan, were one-fourth to one-third bigger and better than pre-war houses, and better equipped. However, the output of building labour was not as high as the country was entitled to expect, and *from now on there would be no inhibitions, implicit* or explicit, on any system of incentives or payment by results in the building industry. The Government expected the building industry to set a new tempo in production. They were not satisfied with the progress in housing; *who could be?* But he resisted the suggestion that it was necessary to reduce the programme. To do so would be gravely to debilitate the national pulse. If the Government had not been able to accomplish all they would have liked, nevertheless they had done a very good job. We were making more progress with housing than any other nation in the world.

Mr. R. S. HUDSON estimated the immediate shortage of houses in this country at 2 million. He charged the *Government with endeavouring to mislead the* by suggesting that the problem was very much than it really was. Mr. Bevan had failed because the dissipation of effort, the slow rate of const and the piling up of excessive costs.

A motion to reduce the Ministry of Health vote £5 was negatived by 258 votes to 111.

Scottish Hospital Board Areas

On July 29 Mr. W. McN. SNADDEN moved that National Health Service (Scotland) (Determination Areas of Regional Hospital Boards) Order, 1947, annulled. Objecting to certain areas defined, he that for years the natural flow of patients from Perthshire had been to Stirling: in 1946 512 were admitted to Stirling Royal Infirmary, but 4 were admitted to the Royal Infirmary for the and city of Perth. Natural flow had been ignored the order, and serious obstacles would be placed in way of efficient hospital administration, not to speak the discontent that would arise.

Sir J. GRAHAM KERR pointed out that under the *arrangements of the General Medical Council* medical student, after passing his qualifying ex tion, would have to spend a year in a resident ap ment at a hospital. To carry out its duties effic each medical school must have a district incl enough hospitals to allow its graduates to put in the year of residence. Further, every medical sc must have at its command sufficient clinical material Yet under this order the population and hospitals were unequally divided between the two approximately equal medical schools of Glasgow and Edinburgh. Glasgow, he was told, was allocated a population of nearly 3 million and Edinburgh a population a little over 1 million. That was not only grossly unfair but would be a tremendous blow to the Edinburgh school, one of greatest in the world.

Mr. J. WESTWOOD, Secretary of State for Scotland, said that if experience showed that the administration could be improved by a change there would be no hesita tion in making a new order. The main consideration had been the convenience of patients. The boundaries were not to be regarded as barriers which patient or medical practitioner could cross, and students from one university could be taught in a hos associated with another university. The Act req that so far as practicable each area should be such hospital and specialist services could be provided convenient association with a university which had school of medicine. The Northern region, which had university within its boundaries, was to be associ principally with Aberdeen University, and with Edin burgh and Glasgow Universities as well, in view of local associations.

It had been represented that the Outer Hebrides should be included in the Western region on the ground that patients and medical practitioners, especially in the southern group of the Outer Isles, had always looked to Glasgow for hospital and specialist services. That position was fully recognised when the boundaries were fixed, but it was nevertheless decided to allocate the Outer Isles to the Northern region to a splitting the areas of the two local health authorities—the counties of Inverness and Ross and Cromarty. Looking to the future, it was felt that the development of the specialist and hospital services in the Northern region, together with the development of improved air communications between t islands and Inverness, would tend to influence the direction of the flow of patients; but the convenience of patients was the prime factor, and there would be no interference with freedom of choice of hospitals, patients, or medical profession alike. So far as the provision of consultant service was concerned there would be collaboration between the regional boards.

Mr. SNADDEN said he did not feel quite happy about t Secretary of State's explanation, but in view of assurance that he would reconsider the whole set if the regional allocation was found to be impractical he would withdraw his motion.

QUESTION TIME

Wheat-extraction and Poliomyelitis

ALPH GLYN asked the Lord President of the Council he had consulted the Medical Research Council effect that the extraction of vitamins from the bread ainable throughout the country had had on the increase ngitis and, infantile paralysis; and if immediate ould be taken to reduce the extraction and to ensure bread content should be the same as in 1939–40.—

MORRISON replied: I am advised that the vitamin of the bread obtainable in this country since 1942 ct, much greater than in 1939-40, since a higher pro- of the nutrient materials in the grain is retained in r. There is no evidence of any relationship between d the incidence of meningitis and infantile paralysis, is a fact that the death-rates from cerebrospinal itis and from infantile paralysis in England and vere much lower in 1945 than in 1940.

. GLYN: If the quality of the vitamins in the bread r than it was pre-war, is the right hon. gentleman that there has been a great deal of misconception out the country? If the increase in mortality as a f this unfortunate epidemic is in no way due to lack nins in the bread, it would be a consolation if he would answer in a way which is perhaps more easily under- y those concerned.

MORRISON: I am scientifically assured that there is nexion between this particular disease and the subject question.

Obituary

WILLIAM EVERETT

M.B. EDIN., F.R.C.S.

liam Everett, senior surgeon to the Royal Hamp- County Hospital, was one of the outstanding nalities of Winchester, and his loss will be felt sections of the community. He had borne with fortitude a number of painful illnesses, and was of the possibilities of the condition from which fered; but he retained so cheerful an aspect that eath, on June 15, had the added shock of surprise ose who did not know the state of affairs.

native of Edinburgh, Everett was a senior medical nt at its university when war broke out in 1914. ld not wait to complete his medical qualification, within a few days had volunteered to serve in the of the R.A.M.C. Shortly afterwards he embarked rance, and he remained in the Army until 1916. at year he was recalled to complete his medical s at Edinburgh, and such was his ability and try that he was able to sit for his final examination e same time as his contemporaries who had not absent on military service. Qualifying in 1917, ined the Royal Navy as a temporary surgeon nant and was posted to a Q "mystery" ship in the erranean. After a period of considerable hazard as transferred to the Naval Hospital in Bermuda, he was in charge of the surgical division and department. On his way to Bermuda he was ed in New York, and was "captured" by the icans to take part in their War Loan campaign. speeches were successful in raising large sums of y for the war. On demobilisation he returned to burgh, where he gained the university prize for ology, and he took his F.R.C.S. in 1919. After work- as senior resident at the Bradford Infirmary, he ied in 1924 the younger daughter of Robert Houston, dinburgh, and moved to Barry, where he had been inted resident surgeon at the Barry Accident pital. He remained there four years, and after a in consulting practice in Cardiff went in 1929 to chester, where he presently joined the honorary of the Royal Hampshire County Hospital.

diagnosis Everett showed care and judgment. an operator his profound knowledge of anatomy, bined with sensitive and dexterous hands, enabled to undertake intricate and delicate operations with ess. He was satisfied with none but the highest dards in his work, and he had an imaginative sym- y for his patients—as indeed for everyone who [illegible] was very fond of children and was particularly successful in gaining their confidence and affection: his artistic abilities were seen not only in his professional work but also in the gay little pictures with which he decorated—using a cake of soap—the windows of rooms occupied by his younger patients. He also had considerable gifts as a lecturer and teacher and was a fluent public speaker. As a colleague he was loyal, staunch, and considerate, and was ever-ready to respond to appeals for help and advice.

In his early days at Winchester he was a keen golfer with a scratch handicap. Another hobby was provided by his garden: he loved flowers, and was very successful in cultivating them. As a raconteur of stories—especially in Scots and Welsh—he was unsurpassed, and he was a most delightful companion. To anyone privileged to enjoy his happy hospitality, it was apparent how much his home life meant to him and in what affection he held his wife and children.

C. J. P.

BEAUMONT HARRY COMERFORD

M.D. DURH.

Dr. Beaumont Comerford died on July 15 after a brief illness. He was born in London in 1864, the youngest son of Lieut.-Colonel Comerford, and was educated at Sherborne School, where he was captain of games and winner of the half-mile, mile, and steeple-chase. From there he went to St. George's Hospital, whence he qualified in 1887. He was house-surgeon and resident obstetric assistant at St. George's, and resident medical officer to the Chelsea Hospital for Women, and was afterwards for many years in practice in Belgravia. He took his M.D. at Durham in 1904, and also the D.P.H. in the same year. He had been honorary medical officer to the National Children's Adoption Association, and to the Imperial Nurses' Club; also medical adviser to the Girl Guides Association. During the 1914–18 war he returned to his old hospital to do duty as out-patient surgeon, to relieve younger members of the staff on war service; he was appointed an honorary governor of the hospital in recognition of his work. In 1905 he married Miss Elizabeth Frances Shaw Woodgate, who survives him, with their son, R. B. Comerford, who has followed his father in the medical profession.

Births, Marriages, and Deaths

BIRTHS

BELL TAWSE.—On July 30, the wife of Dr. A. J. S. Bell Tawse—a *daughter*.

BUZZARD.—On July 28, at Oxford, the wife of Dr. E. M. Buzzard—a daughter.

DOWLER.—On July 31, at Gloucester, the wife of Dr. H. G. Dowler—a son.

FRANKS.—On July 28, in London, the wife of Dr. L. M. Franks—a son.

HAMILTON.—On July 30, in London, the wife of Dr. H. C. Hamilton—a daughter.

KEATINGE.—On July 29, at Beaconsfield, the wife of Major Alan Keatinge, M.C., R.A.M.C.—a daughter.

MACKAY.—On July 30, at Aylesbury, the wife of Dr. E. V. Mackay—a son.

MACLEOD.—On June 28, at Headford, co. Kerry, the wife of Captain A. I. MacLeod, R.A.M.C.—a son.

ROBERTSON.—On August 1, at Southborough, Kent, the wife of Dr. John Robertson—a daughter.

WADE.—On July 31, the wife of Mr. Hilary Wade, M.C., F.R.C.S.—twin sons.

WELLS.—On August 1, the wife of Dr. Christopher Wells, M.B.E.—a son.

WETHERED.—On July 31, at Clifton, the wife of Dr. R. R. Wethered—a daughter.

MARRIAGES

DRAFFIN—MACARTHUR.—On July 26, in London, David Charlton Hornby Draffin, M.B., to Elizabeth Brown Dickson MacArthur.

IRVINE—WALTER.—On July 30, at Guernsey, Robin Eliot Irvine, M.B., captain, R.A.M.C., to Florence Margaret Walter.

MACBAIN—BENNETTE.—On July 19, in London, Gillies MacBain, *D.S.C.*, *L.M.S.S.A.*, to Margaret Bennette.

MACKINNON—FRUIN.—On July 31, at Worcester, John Alexander Mackinnon, L.R.C.P.I., to Lilian Constance Fruin.

PEEL—MELLISH.—On July 26, John H. Peel, F.R.C.S., to Freda Margaret Mellish.

RICE—AUSTIN SMITH.—On July 26, at Woolwich, H. M. Rice, M.B., major, R.A.M.C., to Cheryl Joan Austin Smith.

DEATHS

COOKE.—On July 29, at Shalford, Guildford, Cyril John Chesterfield Cooke, M.R.C.S., D.M.R.E.

FREYER.—On July 29, Samuel Forster Freyer, C.M.G., M.D. R.U.I., lieut.-colonel, R.A.M.C. (retired), aged 88.

Notes and News

SOUTH AFRICAN HEALTH FOUNDATION

In South Africa 25 babies out of every 100 die in their first year, as compared with 3 in New Zealand, 5 in Great Britain, and 7 in Italy. More than half the coloured population live below the poverty line, and, according to a 1942 report, three-fifths of the coloured children are badly nourished or diseased; while their infant mortality is more than 300 per 1000 live births. The Union also has many poor white families; a nutritional survey made six years ago showed that about a third of the European children in the country were malnourished, and one out of every four of them drank no milk at all.

A plan to establish, as a war memorial, a National Health Foundation to combat these ills originated with the South African soldiers during the war, and has been warmly accepted by the whole Union. The Springboks themselves raised some £25,000 from the contributions of South African men and women serving in and with the Forces; and it is hoped that an appeal launched last year to the whole Union will raise the fund to £5 million.

The initial programme is to establish People's Centres for the promotion of health and social well-being, and community living. These centres will encourage better feeding by instruction, food clubs, communal cooking, and help in vegetable-growing. Mothercraft and child welfare will also be taught, and recreation and education are to be arranged for adolescents. A second project is to provide bursaries and grants to men and women of all races to train as health workers. Finally the foundation hopes to arrange a national health campaign, which will provide lectures, films, and travelling exhibitions, besides publishing articles in the press, leaflets, and other educational material.

The foundation is intended to benefit all sufferers, irrespective of race, colour, or creed, but it aims specially at building up the health and improving the living conditions of the non-Europeans, whose needs are greatest.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

The annual meeting of the county-borough group of this society was held in York from July 18 to 21, under the presidency of Dr. W. S. Walton. Dr. J. J. Buchan, Dr. J. Johnstone Jervis, and Dr. Arthur Massey were elected honorary members of the group. Among the addresses was one by Prof. J. C. Spence on the Conduct of Investigations in the Field of Medicine and Social Medicine, in which he suggested that when the new service was in full operation the medical officer of health should have more time and opportunity for research. He urged that the M.O.H. should be inspired by the conception that he was the real community doctor, ready to advise in any field, whether hospitals, education, housing, or even roads. The question must always be asked—is this for the welfare of the citizen? The M.O.H. was responsible for finding the answer; and to provide it he should be prepared to organise, even if he did not himself carry out, the necessary social surveys or sociological research.

EGYPTIAN MEDICINE

In a lecture given in London on July 29 under the ægis of the Egyptian Education Bureau, Prof. Naguib Mahfouz Pasha ably compressed into the compass of an hour the history of medicine in Egypt from the fourth millenium B.C. to the present day. Egyptian medicine had its origin in magic, but the practice of mummification gave an impetus to dissection and anatomy, which led on to physiology and pathology, at a much earlier date than in neighbouring countries, with the result that the Greeks of the third century acquired their medical science from Egypt. Hospitals were established at a very early date in Egypt; patients were bathed and clothed in hospital garb on admission and kept in hospital till cured, if possible; the test of cure was the ability to eat without discomfort a loaf of bread and a chicken. After a rapid review of the changes and vicissitudes of Egyptian medicine, which reached its nadir about a hundred years ago, Professor Mahfouz described the origin and establishment of the school of midwifery (the first students were Sudanese slaves and, on qualifying, were married off to bachelor doctors) and the multiplication of modern universities, which in ten years' time should be able to provide enough doctors for the requirements of the Egyptian people.

BREAST-FEEDING

In an 8-page pamphlet intended for mothers, the N Association of Maternity and Child Welfare Centres and the Prevention of Infant Mortality set out the reasons breast-feeding and the principles on which it should managed. The advice is sound, well arranged, and gives plain and sensible language. Only one small point calls criticism: to dust the breasts with boracic powder, is often gritty and tends to cake when moistened, inadvisable—a good talcum would surely be more appro The pamphlets cost 2*d*. each or 12*s*. 6*d*. per 100, from association at 5, Tavistock Place, W.C.1.

RETROSPECTIVE DEMOGRAPHY

The many admirers of Mr. Ransom Pickard's v and thoroughness know that he does not do things by and that when he set out to estimate the popul Exeter in former days he would neglect no source of inf tion. The result of his researches among baptismal burial registers and tax lists is embodied in a compact interesting little book,[1] which will commend itself students of demography. The grim tale of havoc by epidemics—of plague in earlier times and of typhus, typhoid, and influenza in the post-restoration —is recorded and tabulated in the second part of the to which graphs are appended.

SOCIAL SERVICE IN LONDON

There are now 26 local councils of social service in London area, 4 of which were started during the past In their annual report[2] the London Council of Social Service note that they have also helped at the birth of 20 new com munity associations, and are now in touch with 120 such associations, with a membership of 40,000 Londoners. The also supervise 72 of the 94 citizens' advice bureaux in the region, and are arranging training courses for staff for the bureaux and officers of information centres. The old people's welfare department of the council brought into touch with one another all the voluntary agencies maintaining homes for the old; and, as a result of their meeting, the London Federa tion of Homes for the Aged has been set up, to encourage consultation between the various bodies, and to foster a in standards in the homes. A conference for matrons of such homes is planned. Five local old people's welfare com mittees have themselves established homes, and others are planning to do so.

MILK FOR INVALIDS

The Minister of Food has arranged for patients who have hitherto been receiving household milk-powder on m grounds to be supplied instead with machine-skimmed sweetened condensed milk in quantities with equivalent f value. Application should be made to the local food office

---

University of Oxford

Dr. Sheila T. E. Callender has been appointed to the readership in medicine for seven years from Oct. 1 next.

Dr. Callender took her medical training at St. Andrews Univers where after graduating B.SC. she qualified M.B. in 1938. She held appointments as house-physician and gynæcological and obstetric resident at the Royal Infirmary, Dundee, where she became demonstrator in pathology and later junior assistant clinical pathologist; she was also medical officer to the Blood Trans Service for the East of Scotland. Dr. Callender has spent the four years in Oxford, where she has been house-physician at Radcliffe Infirmary and graduate assistant in the Nuffield depart ment of clinical medicine. In 1944 she graduated M.D. and became a M.R.C.P. She has made a special study of disorders of the blood

At a congregation on July 27 the following degrees conferred:

D.M.—A. R. Norton (in absence).

M.Ch.—E. E. T. Taylor.

B.M.—R. A. Griffiths, C. B. Wynn-Parry, R. A. Cham Christopher Pallis, G. E. Honey, C. C. Kennedy, H. M. I R. H. Balme, Raymond Seidelin, J. H. B. Yule, James Sl Isabel H. Burn, Jean Dutton (all in absence); and B. V. McEn Robert Harvard-Davis, M. S. Kay, R. A. M. Oliver, J. M. Wor A. L. Turnbull, L. J. Cawley, A. G. Parks, Robert Alhadeff, M. L. Lee, Mary P. S. Dalton, Unity R. Allen, Olive P. Frodsham, Je Robertson, Sulammith Wolff.

Samson Wright, Prof. W. R. Spurrell. *Anatomy:* Prof. Thomas
l. *Pathology:* Prof. R. J. V. Pulvertaft, Dr. Archibald Gilpin, Prof.
D. Newcomb, Dr. Kenneth Robson. *Medical anatomy and*
ciples and practice of medicine: Dr. George Hall, Dr. Geoffrey
me, Dr. Reginald Hilton, Dr. Leslie Cole, Dr. James Living-
e. Dr. K. Shirley Smith, Dr. C. B. Levick, Dr. Maurice Shaw,
Thomas Hunt, Dr. J. O. Hawksley, Dr. F. P. Lee Lander, Dr.
lam Brockbank. *Midwifery and diseases peculiar to women:*
D. H. Macleod, Mr. H. L. Shepherd, Mr. R. A. Brews, Mr.
Stacey, Mr. G. F. Gibberd. *Public health:* part I, Prof.
es Mackintosh, Prof. M. E. Delafield; part II, Dr. J. Greenwood
on. *Tropical medicine:* section A, Major-General Sir Alexander
am; section B, Dr. George Macdonald. *Ophthalmic medicine*
surgery: Dr. S. P. Meadows. *Psychological medicine:* part I,
W. D. Nicol; part II, Prof. P. C. P. Cloake, Prof. Aubrey Lewis.
ngology and otology: Mr. M. L. Formby. *Medical radiology:*
W. V. Mayneord (physics), Dr. E. Rohan Williams (radiology),
B. W. Windeyer (radiotherapy). *Anæsthetics:* Mr. Ashley
, Dr. M. D. Nosworthy. *Child health:* Dr. K. H. Tallerman,
A. G. Watkins. *Physical medicine:* part I, Mr. L. H. Clarke,
H. A. Dunlop; part II, Sir Robert Stanton Woods, Dr. W. S. C.
man. *Industrial health:* part I, Dr. J. A. Charles; part II,
R. E. Lane. *Murchison scholarship,* 1948: Dr. J. B. Harman,
G.-D. Hadley.

he Murchison scholarship, held this year in Edinburgh,
awarded to Miss Constance C. Forsyth, M.B. The award
he Baly medal was made to Prof. B. A. Houssay, of Buenos
s, for services to physiology by his researches on endocrine
trol of carbohydrate metabolism. The Bisset Hawkins
lal was awarded to Dr. C. H. Andrewes, F.R.S., for his
arches in typhus and influenza.

he following lecturers for 1948 were appointed:

r. F. M. R. Walshe (Harveian orator), Dr. J. A. Charles (Brad-
w lecturer), Dr. J. F. Nattrass (Lumleian), Dr. C. M. Fletcher
ulstonian), Dr. J. F. Wilkinson (Oliver-Sharpey), Dr. R. Coope
chell), Dr. J. W. Trevan (Abrahams).

ord Moran was elected representative of the college on
National Consultative Committee for the United Kingdom
the Food and Agriculture Organisation of the United
ions.

he following having satisfied the censors' board were
ted to membership:

icences to practise were conferred upon 137 candidates
men and 28 women) who have passed the final examina-
in medicine, surgery, and midwifery of the Conjoint
rd and have complied with the by-laws of the college.
following are the names of the successful candidates:

R. V. Argles, D. A. L. Ashforth, R. W. Attwood, J. M. Barritt,
et B. Bell, J. H. Blackman, E. I. Boxer, D. G. Boyle, G. P. Bradfield, J. P. P. Bradshaw, H. R. Bridgford, T. C. L. Brown, C. M. Browse, Klaus-Ludwig Bucky, Pauline P. Budd, G. H. Bulow, Mario Caturani, K. L. Cleminson, J. M. Clubb, R. O. N. G. Colley, K. J. Covell, K. A. Cowan, W. R. Daniel, A. I. Darling, O. J. O. Davey, A. C. Davies, Leslie Dawson, Jacqueline Domenet, Ada Dudack, M. L. Dyson, Pamela M. Farmer, Loveday Ann Farquharson, Vivian Feldman, T. J. Felix, W. J. Gall, J. H. Garson, Norman Garwood, J. M. Gate, C. E. R. Gee, Edward Gellatly, J. V. Gibson, Joy K. Goodacre, J. D. Greatrex, J. K. G. Grieves, R. H. Griffith, Maxwell Grinstein, Angela W. Hall-Smith, Brian Hardie, Geoffrey Harris, S. J. Harris, Cyril Havard, T. G. Heron, Stella C. Hill, Derek Hobson, J. A. G. Holt, A. P. K. Homayouni, V. E. Ireland, Helen A. Jaques, Barbara Jones, D. G. Jones, A. H. Kasasian, M. R. R. Khan, D. B. Leaming, Josef Lederer, William Lees, Ruth M. Licence, Joyce J. P. Lomas, Terence McCaffry, R. I. MacInnes, J. D. Mackichan, J. A. Mahoney, A. E. B. Matthews, M. D. Mehta, F. W. Millard, L. O. Miller, A. L. Mintz, Barbara A. Moore, C. T. Morgan, Dorothy A. Morgan, A. H. Morris, Meinir Morris, H. J. Moss, G. N. Mulliner, D. J. Oakland, Hugh Owen, Susan H. Palmer, R. T. Parr, R. F. Pearson, A. R. Penn, R. S. Pine, R. C. S. Pointon, Peter Pratt, John Prestt, Violet M. J. Procter, P. K. Pybus, D. M. Rahilly, Pauline Readman, E. R. Reid, Sybil L. Reis, Joan Rendall, David Rider, S. M. Rivlin, J. C. Rushton, A. J. Ruzicka, P. W. Seargeant, P. G. Seear, John Southgate, Sheila J. Spencer, Harold Spira, A. H. Stern, J. D. Stevens, D. B. Stott, Rosa Sutton, P. B. Taylor, J. R. Theobalds, J. M. Thomas, J. M. Titmas, Olive I. Todd, Ruth W. Towler, J. S. Turner, M. H. Turner, O. R. B. Vincent, I. M. Walter, N. D. J. de S. Wijesekera, W. M. Wilkinson, K. P. Williams, L. B. Williams, Sheila G. Wills, Gerald Wiseman, C. H. Wood, Yvette Woodford-Williams, G. R. V. Worrall, Pamela N. Wright, Frank Wynn, R. E. V. B. Young, D. M. Reader, P. G. Treharne.

The under-mentioned diplomas were also conferred conjointly with the Royal College of Surgeons to the following candidates:

Anæsthetics.—D. V. Bateman, O. H. Belam, C. H. Boyd, W. H. F. Boyd, P. R. Bromage, E. K. Brownrigg, Roger Bryce-Smith, J. E. Bulow, Dennis Canter, A. A. Cilliers, R. B. Clayton, F. E. Clynick, S. W. Coffin, E. R. Coleman, P. B. Conroy, C. J. Corcoran, Giovanni Curà, R. M. de Gregory, A. B. Eastwood, I. C. W. English, J. U. Forbes, Andrew Fraser, Eileen M. Gibson, L. J. Goggin, John Gordon, A. H. Grace, P. W. S. Gray, Harry Grenville, J. H. G. Halliday, J. K. Harper, A. W. Hind, A. C. Holms, H. R. Hudd, Gough Hughes, R. M. S. Keir, James Lapraik, C. H. Levick, J. K. Lewis, Mary E. Lloyd, R. E. Loder, J. M. MacCormack, R. M. Mackenzie, R. L. McMillan, S. A. Mason, J. G. Matheson, E. T. Moerch, P. H. Moore, W. B. Neff, G. S. Ostlere, W. J. Patterson, Joseph Psaila, H. J. Richardson, Hilda Roberts, J. D. Robertson, F. R. Russell, C. F. Scurr, N. C. Smiedt, Eugene Thomas, T. C. Thorne, C. E. Tudor, Ambrosine B. Vaughan, Patricia E. Wallace, Mary Watson, H. L. J. Wilson, G. P. Williams, T. M. Williams, T. N. P. Wilton, E. H. Winterbottom, Luise Wislicki, R. B. Wright.

Laryngology and otology.—James Ackerley, J. N. Appleton, L. F. Day, P. F. King, J. A. Langille, J. M. Marquard, Peggy K. L. Orton, O. O. Ring, R. V. Tracy-Forster, K. L. Wilson.

Child health.—Sunilkumar Ray.

Medical radiotherapy.—P. E. S. Palmer.

Psychological medicine.—E. H. Cranswick, J. A. Crawford, P. B. de Maré, J. J. Fleminger, E. H. Hare, A. B. Hegarty, R. F. Hobson, J. G. Howells, Wallace Ironside, John Johnston, G. N. Jones, V. L. Kahan, Julian Katz, L. G. Kiloh, A. B. Kinnier Wilson, C. O. Lack, A. F. McLean, Morris Markowe, D. A. R. Pond, K. C. Royes, Peter Sainsbury, A. B. Sclare, Salo Tischler, P. M. Turquet, A. H. Williams.

Public health.—Averell S. Darling, D. C. Davidson, H. M. Davies, W. J. Elwood, B. L. Frank, R. M. Galvan, G. I. Harding, J. H. Hudson, R. W. Kind, Evelyn M. Lee, N. C. Lendon, Joseph Lister, Daniel MacLeod, R. J. Niven, R. N. Onyemelukwe, J. H. Rayner, C. A. Royde, Benjamin Schwartz, R. W. Scott, Muhammad Shamsuddin, O. H. Shaw, Rahum Shoulman, K. N. Srivastava, W. F. Tierney, K. O. A. Vickery, J. R. D. Williams, H. D. Wilson.

Industrial health.—W. E. Broughton, Caroline J. Brown, Alan Butterworth, J. V. Manning, H. B. Melzer, Niaz-ud-Din, Dorothy Williams.

Medical radiodiagnosis.—J. D. Addison, T. E. Broadbent, A. C. Glendinning, H. J. R. Henderson, R. L. T. Hill, B. N. Klukvin, D. G. C. Macdonald, D. R. Morris, D. H. Nelson, R. L. Quilliam, A. C. Rogers, G. A. Stevenson, R. S. Thorpe, F. R. Turner, C. H. Wood.

Royal College of Surgeons of Edinburgh

At a meeting of the college on July 29, with Mr. J. M. Graham, the president, in the chair, the following were admitted fellows:

J. H. Annan, Paul Baer, C. A. Bathfield, Ben Bellon, Meyer Berkowitz, A. L. Black, Gavin Boyd, W. S. Braidwood, K. O. Burrow, L. S. Cooke, Mary D. Daley, R. H. Dawson, W. H. Ekin, H. S. Gild, A. I. Goodman, I. G. Graber, G. K. Graham, K. E. Guest, R. H. Hannah, D. S. L. Henderson, P. S. Hollings, R. G. Hughes, Jeremiah Hurley, James Hutchison, J. S. F. Hutchison, J. W. S. Irwin, R. E. Isaac, John Joyce, D. J. Jussawalla, J. P. Kelly, H. F. Lowenthal, Philippa M. Ludlam, Brendan McCarthy, Iain McLennan, Stephen Madden, K. L. Marks, F. J. C. Matthews, D. M. Milne, D. G. Morris, F. P. Morris, M. J. D. Noble, John Orr, Frank Paulson, R. E. Pow, T. M. Prossor, Eric Rea, H. O. Rose, J. M. Ross, J. Y. W. Russell, C. G. Saraiya, J. B. Scott, L. B. Scott, Thomas Sergeant, J. M. Shaw, R. T. Simcox, R. V. P. Sinha, W. P. Small, R. J. S. Smith, Thomas Smith, V. G. Springett, Mannie Stein, W. H. Stephenson, Zakaria Taher, S. F. Thomas, J. C. Walker, John Watson, A. G. D. Whyte, J. J. Williams, R. I. Wilson.

Society of Apothecaries of London

A course of 20 postgraduate lectures on modern therapeutics will be delivered in the society's hall at 5 P.M. during October and November. Dates are to be announced shortly.

Royal College of Surgeons of England

A meeting of the council was held on July 31, with Sir Alfred Webb-Johnson, the president, in the chair. It was decided that candidates for the final F.R.C.S. examination must have served a period of postgraduate surgical training of 12 months in posts approved by the college: 6 months of this period must have been occupied in residence in a hospital recognised for the purpose.

Diplomas of membership were granted to the candidates named under the Royal College of Physicians, with the exception of Hugh Owen, to whom membership had been granted previously.

Diplomas were granted, jointly with the Royal College of Physicians, to the candidates named under the Royal College of Physicians.

Royal College of Obstetricians and Gynæcologists

At a meeting of the council on July 26 Mr. W. Gilliatt was re-elected president. The following officers were also re-elected: vice-presidents, Sir William Fletcher Shaw and Mr. J. M. Wyatt; hon. treasurer, Mr. A. A. Gemmell; hon. librarian, Mr. F. W. Roques; hon. curator to the museum, Mr. Aleck Bourne. Mr. H. G. E. Arthure was elected hon. secretary.

The following candidates were elected to membership of the college:

S. J. Aptekar, H. B. Bagshaw, G. H. Bancroft-Livingston, Solomon Bender, Isabella R. Bishop, J. T. S. Brown, Gwendoline E. Cockrem, J. M. Corston, G. A. Craig, K. J. R. Cuthbert, R. W. Danziger, B. C. Dastur, Josephine A. Davidson, N. E. C. de la Hunt, W. P. G. Dickson, I. A. Donaldson, Sara M. Field-Richards, T. B. FitzGerald, J. B. Fleming, I. T. Fraser, A. M. Giles, A. M. Graham, E. F. B. Hamilton, Lois E. Hurter, D. W. James, Eileen I. Jamieson, R. J. M. Jamieson, D. H. Lees, Max Lipsitz, G. I. Louisson, William Love, Joan E. W. Mackie, C. J. MacKinlay, J. T. Mair, Parvati Malkani, W. G. Mills, P. R. Mitchell, Mary L. Neville, E. R. Ormerod, H. G. Page, S. S. Parlee, Nancy Perry, E. E. Philipp, J. G. Pritchard, E. E. Rawlings, Elizabeth M. Rose, Dorothy M. Satur, D. A. F. Shaw, D. J. N. Smith, James Walker, Ada S. Wong.

Milk for Children

In an administrative memorandum (no. 238) issued by the Ministry of Education the permitted quantity of school milk for children attending grant-aided nursery-schools will, from August 1, be two-thirds of a pint per day. From the same date one pint of milk daily at 1½d. per pint will be available from the registered suppliers for children between the ages of 5 and 16 who are unable to attend school by reason of mental or physical disability. Forms of application (WF.42) are obtainable by parents or guardians at local food offices.

British Council for the Welfare of Spastics

With the support of the Ministry of Education and of other Government departments the British Council for the Welfare of Spastics has been constituted to act as a central advisory and coördinating body for all activities in England and Wales directed to the education, training, treatment, and well-being of sufferers from cerebral palsy. In an administrative memorandum (no. 239) the Minister of Education urges local education authorities to contribute to the cost of the council's activities, and he undertakes to recognise for grant expenditure by authorities on the basis of contributions up to 10*s*. for every 1000 pupils between the ages of 2 and 18.

Cancer Campaign in U.S.A.

With the passage by Congress of legislation more than tripling appropriations for research and control of cancer, and bringing next year's budget of the National Cancer Institute in Bethesda, Maryland, to $14 million, the United States Public Health Service announces plans that will place cancer in the forefront of the government's medical research and control programme. On the institute's budget $4 million is allocated to efforts to increase the effective use of present methods of diagnosing and treating cancer. It is estimated that while a quarter of cancer patients are cured today another quarter could be cured if they had early treatment.

R.A.M.C. Prize

The consultants to the Army in the late war have presented a sum of money to the R.A.M.C., in order to found a Consultants' Prize. The first award will be made in 1948, and will be of the value of 25 guineas. The prize is to be given for an essay of not more than 10,000 words based on the author's personal experience of a professional subject between 1939 and 1946. Entries should be submitted through the usual channels so as to reach the hon. secretary, R.A.M.C. Prize Funds Committee, R.A.M. College, Millbank, London, S.W.1, by August 1, 1948.

Reablement in L.C.C. Hospitals

At a meeting last week the London County Co accepted a recommendation by its hospitals and me services committee that a physician for physiotherapy be appointed at a salary of £1000 a year.

Free Training for Physiotherapy Teachers

The Ministry of Health announces (circular 113/4 further scheme for assisting physiotherapists who w become teachers. Tuition fees will be paid and a main allowance granted to the candidates selected, who will t four-month course in London between December and

Ministry of Education

The medical branch of this Ministry is now to be kno the "special services" branch. The branch deals wi school meals service, the school health service, and special tional treatment for handicapped pupils. Communi should be addressed to 15, Chesham Place, London, S.W

Protective Covering for Food

Chemists of the United States department of agri have developed a new edible protective covering for meat other food products. Inexpensively made from citru or apple pomane, it forms an airtight covering fo dipped into a solution. The film covering is dissolved the food is boiled and may be eaten when it is fried or

Mobile Surgical Unit for Birmingham

A mobile surgical unit, presented by the Austin Company Ltd., is to start work in Birmingham on Augus It will be based on the Accident Hospital and will serve area within a 12-mile radius of the city. Equipped wit operating-theatre, it will transport surgeon, anæsthetist, nurse to the site of serious accidents where immediate surgical treatment is required.

Dr. R. C. S. Dow has been appointed honorary surge dentist to the King in Scotland.

Medicine in the Colliery.—Referring to our paragr of July 26 (p. 158) on the establishment of medical treat centres in the coal-mining industry, the Butterley Co. informs us that at least two companies in the East Mid had established medical services long before 1945, when the Ministry of Fuel and Power began to set up treatment ce Ten nurses are working at collieries formerly controlled these companies.

Appointments

Anderson, Geraldine, M.R.C.S.: pathologist, Bedford C Hospital.

Cronin, J., F.R.C.S.: asst. surgeon, orthopædic, fracture, traumatic department, Prince of Wales's General Ho London.

Grahame, E. W., M.D. Glasg., F.R.C.S.E.: medical superintende General Hospital, Middlesbrough.

Heller, G. K., M.D. Prague: asst. M.O., Friern Hospital, N Southgate.

Millen, R. M., M.D. Glasg., M.R.C.O.G.: obstetrician, Chase F Hospital.

Morrissey, W. J., M.B. N.U.I.: asst. school M.O. and asst M West Bromwich.

Pickard, Cecil, M.B. Leeds: radiologist, St. James's Ho Leeds.

Sharp, H. S., M.B. Camb., F.R.C.S.: ear, nose, and throat su Putney Hospital.

Simmons, H. T., M.D. Manc., F.R.C.S.: asst. surgeon, Man Royal Infirmary.

West, L. R., M.B. Adelaide, M.R.C.P.: chest physician, Sully Tu culosis Hospital, Cardiff.

Maudsley Hospital, London:
- Anderson, E. W., M.D. Edin., F.R.C.P., D.P.M.: physician
- Davies, D. L., B.M. Oxfd, D.P.M.: senior registrar.
- Warren, Wilfrid, M.B. Camb., D.P.M.: senior registrar.

Northampton General Hospital:
- Bryan, W. E., M.R.C.S.: morbid anatomist.
- Gosset, I. H., B.M. Oxfd: consultant pædiatrician.
- Welsh, Abigail, M.B. Dubl.: consultant anæsthetist.

Hull Royal Infirmary:
- Eddie, T. S., M.B. Melb., M.R.C.P.: physician.
- Stewart, T. M. J., M.D. Edin., D.C.H.: asst. physician.

Colonial Service:
- Anderson, T. F., O.B.E., M.D. Camb., D.T.M. & H.: senior med officer-in-charge, British Somaliland.
- Carothers, J. C. D., M.B. Lond., D.P.M.: specialist psychi Kenya.
- Ferguson, S. C., L.R.C.P.I.: M.O., Nigeria.
- Grattan, E. O'D. C., M.B. Camb., F.R.C.S., D.T.M. & H.: Kenya.
- Hernet, Edmund, M.D. Poznan: district M.O., Windward Is
- Hudd, H. R., M.B. Wales: M.O., Tanganyika.
- Thomson, I. G., M.B. Aberd.: M.O., Nigeria.
- Webb, E. J. E., M.B. Lond.: M.O., Zanzibar.
- Wright, F. J., M.D. Camb., M.R.C.P., D.T.M. & H.: me specialist, Kenya.

CRAMP AND SALT BALANCE IN ORDINARY LIFE

Sir ARTHUR J. HALL
M.D. Camb., F.R.C.P.
RITUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF SHEFFIELD

AMP, though a common source of pain which at times interfere seriously with sleep or even with health, hitherto received little attention in medical literature, in many standard textbooks of medicine is not even tioned.

a personal inquiry about its frequency in 200 nal persons, aged 15–80, with equal numbers of either it was found that 56% had suffered from cramp and had not. The percentage of those who had not had np was rather higher in women than in men. Of e aged 50 or more 70% had had cramp and 30% not, the percentage of those who had had cramp g rather higher in women than in men, because of association with pregnancy.

hese few figures seem to show that in this climate rly three-quarters of the population have cramp at e time in their lives. The degree of cramp varied ely; 6 persons had only had one fulminant attack, ally following violent exertion; in 15 it was frequent troublesome; in most it was not more than a minor sance.

FORMS OF CRAMP LINKED WITH SALT IMBALANCE

ertain forms of cramp are known to be associated h a disturbance of salt balance: Rogers (1909) wed that cholera could be successfully treated with ines, whereupon the cramp disappeared; Moss 24) and others showed that there was a direct contion between miners' cramp and their loss of salt by eating; and McCance (1936) found experimentally at one of the effects of completely withholding salt m the diet is a painless cramp, which disappears when t is given again. Cramp did not develop in one person o could not be made experimentally salt-free.

In these three very different conditions the common tor is salt depletion, whether by diarrhœa in cholera, ofuse sweating in the miner, or complete cessation salt intake, besides increased sweating in McCance's periments. Since diarrhœa, excessive sweating, and insufficient intake of salt may arise in ordinary life, salt balance may be upset, leading to cramp.

At first sight the cramp seen in these three special aditions seems to differ so much from cramp in ordinary that they cannot be the same. In cholera muscles various parts of the body are affected at short intervals, d the pain is very severe; in the miner cramp is usually afined to the muscles of the legs and abdomen, the ack is single and soon passes off when the miner is ried out of the hot seam, and the pain is very severe; McCance's experiments, as in cholera, the distribution wide, for cramp may affect any muscle when put into tion, but it differs in the complete absence of pain. e muscles affected merely go stiff, and the cramp sses off when they are gently rubbed.

Each of these types of cramp, however, is seen in dinary life: 6 of the 200 cases investigated had had dden intense or fulminant attacks as crippling, for e time being, as those in the miner; and painless amp, closely resembling that described by McCance, not uncommon in persons who also get the painful m in the legs at night in bed. The following are amples of each kind.

vere or fulminant

Case 1.—A male, aged 20, had, towards the end of a strenus football match, sudden intensely severe cramp in both legs; he fell to the ground and had to be carried off the field. He had never had cramp before and has not had it since.

Case 2.—A male, aged 25, had, after a 38-mile bicycle ride, while sitting at tea, a sudden severe cramp in both legs. The pain brought him to the floor. No cramp in any form either before or since.

Painless form

Case 3.—A male, aged 60, for many years had occasional cramp in bed at night. Often, after any extra use of the arms in the day he has painless cramp in the fingers in the evening, when holding a book, playing a violin, holding cards, &c. The hand or a single finger merely goes stiff, and is relieved by being pulled straight.

Case 4.—A male, aged 55, who often has painful cramp in legs in bed at night, has painless cramp in fingers in the evening after gardening in the afternoon.

It is unnecessary to give details of the rest of the seven persons in which this painless type occurred; in women it often follows much knitting or sewing. In some it comes on writing.* A road-sweeper, who has painful cramp in the legs when in bed, stated that, after an extra-hard day's wheeling and brushing, his fingers go stiff in the evening, when he is sitting quietly at home. It is painless, and he just pulls them straight. These cramps in the hands usually come in the later part of the day, following their extra use. There is no reason to think that they differ in kind or in origin from the painful form which, at other times, affects these persons in the legs. Even in these larger muscles the amount of pain varies considerably in different attacks.

RELATION OF SALT TO ORDINARY CRAMP

If, then, these cramps are akin to those which have been shown to be related to salt imbalance, the question arises whether it is a disturbance of salt balance or some other factor that plays a part in the cramp of ordinary life. As yet there is no evidence in the great majority of "cramp-positives" either of a shortage in their salt-intake or of excessive loss of it by excretion. In the 200 persons mentioned above, the 73 who had cramp took a normal, or more than normal, amount of salt with their meals, whereas 5 who never took any salt on their plates had never had cramp in their lives.

Thus, though the question of salt balance does not seem to enter into most cases of cramp in ordinary life, in some instances it seems to do so, and in a few it certainly does. Sometimes it appears to be a sudden deficiency due to loss by sweating either because of a spell of hot weather, or excessive exertion, or both. This may be the explanation of the 5 fulminant cases, among the 200 persons mentioned above, in whom a single severe attack, comparable to that seen in miners, followed strenuous muscular activity. A striking example of this is recorded by Gregson (1944):

> After a week of very hot weather a youth, aged 17, who had never had cramp before, began to have violent recurrent cramp in the arms and legs. It was completely stopped by giving him salt and water. He had been sweating profusely and, what is of special interest, "he never takes salt with his food because he dislikes it."

In a recent letter Dr. Gregson states that, since this attack, the youth, on Dr. Gregson's advice, has taken salt regularly, and that for at least two years after the attack, when Dr. Gregson last saw him, there had been no recurrence of cramp.

In these instances it seems that it was the temporary salt-loss by the skin which played the predominant part. In the following three cases, however, it was the diminished intake which was entirely or largely the cause of the cramp.

Case 5.—On May 31, 1938, I was asked by Dr. A. H. Dunkerley, of Westerham, to see with him an elderly widow, about 75, who, twelve years before, had had acute epidemic encephalitis followed by parkinsonism. For the last two years she had been on "high atropine" treatment with great benefit and, though a semi-invalid, could get about a little every day.

---

* This is different from so-called writer's cramp, which would be better called an occupational neurosis.

During the last six weeks or so a new symptom had arisen *in the form of violent cramp at the back of the knees and* thighs. It came on every night as soon as she was put to bed, about 6.30 P.M., and was relieved by rubbing, only to recur in a few minutes. This might go on for five or six hours. She had never had cramp in her life before this.

She had had no severe diarrhœa; she was probably sweating less than normal, since she was taking very large doses *of atropine daily; she was not doing violent muscular work;* there was thus nothing to suggest a disturbance of salt balance by excessive loss, and there only remained the possibility that her intake of salt might be deficient.

It then transpired that for ten years, on the advice of a specialist, she had been having a "salt-free" diet. No salt was put into her food in cooking, and she took none on her plate.

This had been a great deprivation to her when first begun, as she had always been very fond of salt and taken more than most people at her meals. In time it had become such a part of the household régime, that even Dr. Dunkerley, who had attended her for the last three or four years, had never heard of it.

We agreed that, before making any other change in treatment, she should begin taking salt with and in her food again. Within a week the attacks of cramp ceased entirely, and in January, 1940—i.e., twenty months later—Dr. Dunkerley writes: "She has never been better, has put on a stone in weight, and has not had any further attacks of cramp."

A later note stated that cramp never recurred up to the end of her life, two or three years later.

It is not often in the practice of clinical medicine that the conditions approach so nearly to those of an experiment. The patient was always under the close observation of a devoted daughter, who gave up the whole of her time to looking after her. The daily routine was always the same. Meals were all taken at home, and the preparation of the salt-free diet had been for ten years a daily duty. The surprising thing is that the patient had maintained her salt balance for so long; possibly the regular intake of atropine, with consequent reduction of normal sweating, may have played some small part in diminishing the loss of salt through the skin.

In the following two cases, although the effect of supplying salt in the diet was less complete than in the previous instance, yet sufficient relief followed to make it clear that the cramp was in some way associated with a disturbance of the salt balance.

Case 6.—A man, aged 45, seen on March 27, 1940, had first had cramp 17 years earlier after sprinting to catch a tram. It was in the left thigh and extremely painful.

Since then it had been a more or less constant source of trouble, chiefly in the left leg, when in bed, and occasionally in the forearm, when using tools in the daytime. From time to time it had been so frequent, and so severe, as to interfere seriously with his life as an active business man.

At one time he had been advised to try a sea trip to the Canaries, from which he had got considerable relief for some months.

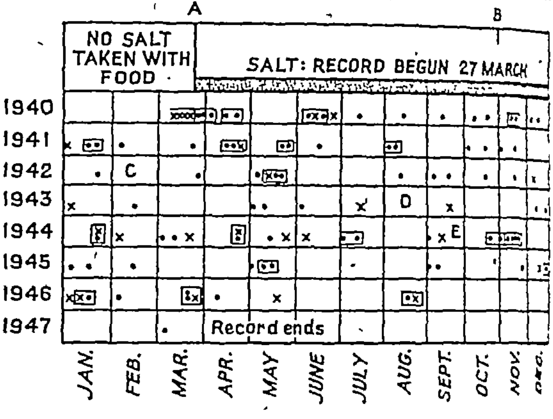
About 1935, however, it had again become so bad that, after consulting several physicians without relief, he underwent manipulation of the left leg, the part usually affected. For this he was in a nursing-home for three weeks. It was evidently a severe wrenching, done under anæsthesia, and for some time afterwards he could only walk with difficulty.

This also was followed by relief from the cramp for a considerable time. Latterly, however, cramp had returned, and had now again become so frequent and so painful that he dreaded going to bed at night.

Except for this he was in sound health and carrying on full active work. Asked about his diet he said he never took salt, because he hated the stuff, and that at home "they were not allowed to put any into his food."

I prescribed capsules containing sodium chloride gr. $7\frac{1}{2}$, of which he was to take two thrice daily. He was not aware of their contents.

On May 9 the report came that, for the first week after beginning the capsules, there had been two or three twinges of cramp in bed at night, but for the last three weeks he had not had any attack of cramp.



Cramp chart (case 6): A, sodium chloride gr. 90 daily in capsules; B, salt daily in and with food; C, sodium bicarbonate gr. 10 at night; D, bicarbonate left off about this time; E, bicarbonate renewed, and taken regularly till end of record. A cross indicates a severe attack of cramp; a dot a mild one.

At the time of his first visit, he promised to record in his diary the dates and hours of all his attacks. This he has done faithfully for the last seven years and has reported the dates to me at regular intervals during that time (see accompanying figure).

He was soon told the nature of his capsules and advised to have salt put in his food and to take it with his meals.

The chart, prepared from his seven-year record, shows that the cramp has not disappeared entirely, but that it comes only at intervals, sometimes of several weeks, and that it is then usually only very mild, though, as the chart shows, *more severe attacks do occur at rare intervals.* In May, 1942, he said "I have nearly forgotten the whole thing."

In January, 1942, as it seemed possible that his own idea of taking salt might be insufficient, he was given sodium bicarbonate gr. 10 in tablets to take at bedtime. He did this regularly for a few weeks and then gave *it up* of his own accord.

All went on much the same until 1944, when the attacks began to be rather more frequent and more severe. He was therefore advised to take the bicarbonate capsules again, and to continue to do so regularly. He has done this since September, 1944, and, as is seen from the chart, the attacks have *diminished* both in number and severity, until during the twelve months from April, 1946, to April, 1947, there were only five, two of which occurred within four days of one another, followed by a free interval of six months.

The chart (see figure) *shows that* the cramp tends, when it does occur, to do so either on successive days or at intervals of from 2 or 3 days to a week or so. Strümpell (1923), himself a sufferer from cramp, mentioned this feature in his own case. Cramp might be absent for months and would then occur repeatedly for several days. These cramp periods are very similar to the "units of epileptic activity" described by Griffith and Fox (1938). In a paper on epilepsy by me (Hall, *1939) there is a chart in which these units* are shown very clearly. Its similarity to the accompanying *chart of cramp* is rather striking.

The temporary relief from cramp which followed manipulation may be *attributed to the fact* that for some time afterwards it made him so lame as to put out of action that particular combination of leg muscles, whose previous over-use during the day had been followed by cramp in the night. Whatever amount of his improvement may have been due to the manipulation, it cannot be overlooked that, during the three weeks that he was laid up in a nursing-home and during his previous sea trip to the Canaries some years before, all his meals *would be cooked with the usual* amount of salt. In a man so dependent on a sufficient intake of salt, these periods away from home *probably played an* important part in reducing the amount of cramp.

Case 7.—A man, aged about 65, actively occupied and in l vigorous health seen on April 29, 1945.

For the last four or five years he had had troublesome amp in the legs at night, and (what annoyed him more) came in painless form in his fingers when writing, so that had had to type his private correspondence. He had ver had cramp in his life before this.

On inquiry it was found that he never took salt on his plate, he disliked it. He was advised to begin taking it th all his meals, but, as it seemed that he might not do so gularly or sufficiently, he was also ordered two tablets of dium bicarbonate gr. 5 to take every night.

r February, 1947—i.e., nearly two years later—he reported at, since he had begun treatment, there had been no further amp in the fingers when writing. He had put away his pewriter and wrote all his correspondence as before.

Cramp in the legs at night had only occurred at long tervals. The first time was on July 11, 1945, and again, ur days later, on July 15,† three months after beginning eatment, next on Jan. 16, 1946, while getting into bed. nce then there had been practically none. He had given taking the bicarbonate after a time, and now took salt ith his meals regularly.

The reason for giving bicarbonate of soda in the two tter cases was that it seemed doubtful whether either the men would take enough salt with his meals, seeing at both of them disliked it and had not been in the bit of taking it on their plates. The value of combining with sodium chloride in the treatment of dogs from hich the suprarenal glands have been removed was lvocated by Harrop et al. (1935), and one cannot nore the fact that from time to time sufferers from iopathic cramp on whom reliance can be fully placed ve found relief from its use.

SUMMARY

Cramp occurs in three special conditions in which it is nown to be due to salt depletion.

In the large majority of those who suffer from cramp in dinary life there is, as yet, no evidence of a disturbance salt balance.

In a very small minority there is definite evidence of ich disturbance, either by diminished intake, increased utput, or both together, as shown in the present cases.

The very severe and the painless types of cramp seen the three special conditions are met with from time to me in the cramp of ordinary life.

Whatever may be the therapeutic value of a "salt-ee" diet, it is not without risk of causing cramp if rried beyond a certain degree.

"... The public has become far more aware of science, and ientists of the public, thanks largely to the drama ... of he atom bomb. But this awareness, on the public side, is some ways even worse than indifference, for the people hink of science more and more as a sort of black magic, hreatening their traditions continually and likely to blow hem up momentarily. Even at best, science to them is the reator of comfort-improving gadgets or of miracle drugs, ever an objective attitude and a rational attack on problems. ot it is the attitude and method of science which can save ociety, even more surely than some products of science can lestroy it. It is also true that in the past decade many scienists have accepted and struggled to perform their obligations o the greater community of which scientists are part. ... But, y and large, the scientists and technologists remain somnoently unaware of the world beyond their equations, spectronoters, microscopes, or oscillographs. ... Scientists need a roader educational base before ascending their towers of pecialisation."—R. W. GERARD, *Science*, July 11, p. 23.

HUMAN-MILK BANK IN A MATERNITY HOSPITAL *

JOYCE WRIGHT
D.M. Oxfd

ELSIE M. C. EDWARDS
S.R.N., S.C.M., R.S.C.N.

From the University College Hospital Medical School and the Obstetric Hospital, Huntley Street, London

THE organisation of a human-milk bank in an American maternity hospital was described in 1944 by Ripley.[1] Excess milk from mothers in the lying-in wards was collected, pooled, and boiled for ten minutes. After cooling, its original volume was restored with sterile distilled water. The milk was then poured in 3-oz. amounts into sterile bottles which, after capping, were stored in a freezing-cabinet at −10°C. When required for infant feeding, the milk was thawed and boiled again.

A human-milk bank was started in June, 1944, in a twenty-bed ward of the Obstetric Hospital, Huntley Street. Most of the patients in the ward were primigravidæ, but multiparæ with complications were also admitted. The stay in hospital was ten days for a normal patient. From November, 1944, to April, 1945, a frozen human-milk bank was run for experimental purposes in the laboratory.

THE WARD MILK-BANK

The human milk was collected by the method described by Wright.[2]

Heat Treatment and Storage of Milk.—The apparatus required is as follows:

Ice-cream freezing-cabinet regulated to −12°C.
Enamel saucepan with lid.
Four-ounce and eight-ounce Soxhlet feeding-bottles of heat-resistant glass.
Dressing drum (or biscuit tin).
Adhesive tape ½ in. wide.
'Cellophane' squares for capping bottles.

The feeding-bottles were plugged with cotton-wool, wrapped in plain lint, and placed, together with the cellophane squares, in the dressing drum or tin, which, together with its contents, was sterilised in the operating-theatre autoclave.

Milk obtained from the mothers was immediately pooled and taken to the ward kitchen, where it was brought to the boil in the lidded saucepan. It was allowed to cool slightly and was then poured into the sterile feeding-bottles; in filling the bottles allowance was made for expansion of the milk during freezing. The bottles were replugged and capped with the cellophane squares, and adhesive tape was bound tightly round the neck of each bottle to keep the cap in place. Date of collection, quantity of milk, and donors' names were recorded in a book against a serial number, which was also written on the adhesive band on the bottle. The bottles of milk were then placed in the freezing-cabinet for storage.

Infant Feeding with Stored Milk

When required for use, a bottle of frozen milk was taken from the freezing-cabinet, and the milk was thawed by placing the bottle in cold water, which was gradually warmed with hot water from the tap. The milk was then brought to the boil in a lidded saucepan. It was poured into sterile feeding-bottles, and a boiled rubber teat was placed with boiled forceps over the open end of each bottle. The milk was adjusted to body temperature, the necessary vitamins were added, and the milk was then used for infant feeding.

Amounts and Distribution of Stored Milk

Human milk from the ward bank was successful in the feeding of premature infants in the Obstetric Hospital, and of infants with gastro-enteritis, pyloric stenosis, and nutritional disorders in the children's wards of University College Hospital.

---

* A report to a special committee appointed by the Medical Research Council to advise on problems relating to the conservation of human milk.

[1] Ripley, W. *J. med. Soc. N.J.* 1944, 41, 43.
[2] Wright, J. *Lancet*, July 26, p. 121.

In the twelve months from June, 1944, to June, 1945, human milk stored in the ward bank was distributed as follows:

	fl. oz.
Premature and other infants in the Obstetric Hospital	462
Sick infants in the children's wards	380
Infants under care of district midwives . ..	36
Laboratory tests	16
Total	894

This amount was additional to that used from day to day for infant feeding. The quantities preserved do not represent supply and demand during normal times, because for ten months of this period London was under air attack, and for part of the time the hospital was evacuated.

Bacteriological Findings

The bacteriological examination of samples from the ward milk-bank was limited by the shortage of human milk resulting from war-time difficulties. For testing surplus milk which could be spared for the purpose, 'Yeastrel'-milk-agar pour-plates were made in duplicate, each with 1 ml. of milk, and incubated aerobically for three days at 37°C. Eight milk samples from the ward bank were tested; three colonies of aerobic spore-bearing bacilli grew from one, and one colony of *Sarcina lutea* from another. The remaining plates were sterile. Pour-plates, similarly prepared but anaerobically incubated, from four banked milks were sterile.

THE LABORATORY MILK-BANK

An experimental human-milk bank was set up in the laboratory in November, 1944. Pooled milks for the bank were obtained from the Obstetric Hospital and from two other maternity hospitals.

Heat Treatment and Storage of Milk

Milk samples from the Obstetric Hospital were dealt with in the laboratory within an hour of collection; those obtained from other hospitals were subject to two or three hours' delay. A portion of each batch of pooled raw milk was set aside for bacteriological examination. The remainder was brought to the boil in a saucepan and then poured in equal amounts into each of three sterile bottles. These were then closed with sterile bungs or screw caps, capped with sterile cellophane, and placed, when cool, in the freezing-cabinet at −12°C. Eleven pooled milk samples were banked.

Bacteriological Investigation of Raw Milk

Each of the eleven raw-milk samples was planted on two blood-agar plates, one of which was incubated aerobically and the other anaerobically for two days at 37°C. Subcultures and tests for bacterial identification were then made.

The following bacterial flora was found:

Unpigmented micrococcus (11 samples); yellow micrococcus (4); golden micrococcus (2); sarcina (1); *Staph. aureus* (coagulase-positive) (7); alpha- and non-hæmolytic streptococcus (8); *Bact. coli* (2); *Bact. alcaligenes* (4); *Bact. aerogenes* (4); aerobic spore-bearing bacillus (1); diphtheroid bacillus (3); monilia (1); flavobacterium (1).

Sterility Testing of Boiled and Stored Milk

Sterility tests of each milk sample were made immediately after boiling and subsequently at the 4th, 8th, and 12th weeks of storage at −12°C; 1 ml. of each sample was pipetted with sterile precautions into each of six petri dishes. Pour-plates were then made with yeastrel-milk-agar; three plates of each batch were incubated aerobically and three anaerobically for three days at 37°C.

From one sample tested immediately after boiling three colonies of micrococci grew; all plates from the remaining samples were sterile. Eighteen bacterial colonies developed from the total of 198 ml. of milk tested at monthly intervals during storage. The count of the stored milk was therefore less than one colony developing per 10 ml. Seven of the eighteen colonies were aerobic spore-bearing bacilli, an organism which might be expected to survive boiling; one was a mould; and the remaining ten were micrococci. Sterility testing was carried out in a large laboratory; it is therefore possible that some of the colonies resulted from aerial contamination of the plates.

Flavour of Boiled and Stored Milk

Each milk sample was tasted immediately after boiling, and subsequently at the 4th, 8th, and 12th weeks of storage at −12°C. Immediately after boiling, all the samples had the normal flavour of fresh breast-milk, except one which tasted "soapy" throughout the test. Six of the milks tasted slightly rancid at the 12th week of storage in the freezer, and one as early as the 8th week, but deterioration in flavour was so slight as to be hardly detectable.

DISCUSSION

A frozen human-milk bank in a maternity ward is a useful method of preserving surplus breast-milk for times when the demand for its use in infant feeding is greater than its supply by the lying-in mothers. It is particularly useful in a general hospital with both maternity and children's wards. Apart from the initial cost of an ice-cream freezing-cabinet, expense is negligible. Milk, after boiling, retains a very low bacterial content during storage at −12°C; it keeps a good flavour for eight weeks of storage, with only an almost undetectable deterioration between that time and the 12th week.

One or two safeguards need to be mentioned. The human-milk bank should be in the sole care of the ward sister, who should understand thoroughly the correct procedures for the collection and storage of milk. There is a risk of bacterial growth and production of enterotoxin in raw milk kept at room temperature; human milk should, therefore, be heated *immediately* after collection.

SUMMARY

The establishment of a frozen human-milk bank in a maternity ward and of an experimental milk-bank in a laboratory is described.

Human milk for the ward bank was obtained from the mothers in one twenty-bed ward. It was collected by a clean ward technique, pooled, boiled, and stored in an ice-cream freezing-cabinet at −12°C.

In twelve months 894 fluid oz. of milk was stored in the bank and successfully used for feeding premature and other infants in the maternity hospital and sick infants in the children's ward of the general hospital. The investigation was made during a period of enemy activity and hospital evacuation; normally, much larger quantities of milk would be available for preservation.

Human milk for the laboratory bank was obtained from the Obstetric Hospital and from two other maternity hospitals. It was heated and stored in a similar manner to the milk in the ward bank.

The sterility and flavour of the milk in the laboratory bank were tested immediately after boiling and at the 4th, 8th, and 12th weeks of storage. There was a very slight deterioration of flavour between the 8th and the 12th weeks of storage.

The frozen milk bank proved a useful method of preserving human milk for infant feeding.

We wish to thank Prof. F. J. Browne for his interest in the work, and Messrs. J. Lyons and Co., Ltd., for the loan of three ice-cream freezing-cabinets. We are particularly indebted to Mr. Arnold Walker; investigations on the conservation of human milk were made at his suggestion and resulted from his original work on this subject.

NIGN PNEUMONIA IN WEST AFRICAN SOLDIERS

A. S. HOLLINS
O.B.E., M.D. Camb., M.R.C.P.
STANT PHYSICIAN, NATIONAL TEMPERANCE HOSPITAL, ONDON: LATE TEMPORARY LIEUT.-COLONEL, R.A.M.C.

HIS paper is based on observations made on 172 West ican soldiers suffering from pneumonia in a military pital in Sierra Leone between August, 1944, and il, 1945.

lany writers have drawn attention to the high incice of respiratory infection, particularly pneumonia, ong African natives. On the whole the type of pneunia described among civilian Africans is more serious n that described among military personnel. Raper 44) records a serious type among East African troops East Africa, but MacNaught and Murray-Lyon (1943) Simpson (1944) comment on the benign form ountered among West African troops in West Africa. he most striking feature of the present series was that ost every case was relatively mild; mortality was ligible, convalescence very rapid, and complications remely rare.

enign forms of pneumonia, comparable to the *nes frustes* of other diseases, have been recognised for ny years: Woillez gave his classical description in 2. Lately much has been written on benign pneunia-like conditions under such names as soldiers' umonia, pneumonitis, focal pneumonia, and primary pical pneumonia. It is improbable that all these ignations cover the same entity, but gradually the m primary atypical pneumonia has been accepted and regarded as at least a syndrome, probably of virus gin. It seemed possible that many cases of this series ght prove on investigation to belong to this group.

The scope of investigation was limited by the fact that subjects were picked young men who had been sed as fit for military service and were living under d conditions with an adequate diet. The conclusions refore do not necessarily apply to African natives in eral.

ASSESSMENT OF CLINICAL TYPE

The term "pneumonia" has been used in the broadest se to include all cases of inflammation of the substance the lung in which there was clinical or radiological dence of an alveolar exudate. The main approach s clinical, and cases were primarily classified on purely ical grounds into four main groups—classical, pical, abortive, and bronchopneumonic. The various oratory and radiological findings were afterwards related with this clinical classification by a series of les from which extracts are included. Inevitably it s difficult to classify some of the borderline cases, and principal clinical features adopted as standards were follows:

lassical Group.—An acute chest picture. Sudden onset, h temperature, productive cough, often signs of consolidan, usually a fall of temperature by crisis and response to cific chemotherapy.

typical Group.—Gradual onset, general malaise, headache, derate fever, and paroxysmal cough, often unproductive. e chest signs are few, signs of consolidation are rare, the nperature usually falls by lysis, there is no response to cific chemotherapy, and complete resolution and recovery y be slow.

bortive Cases.—Acute onset with a clinical picture suggest a classical pneumonia but with a minimum of physical ns in the chest. Within about 24 hours the temperature ls to normal; abnormal physical signs, if any, rapidly appear; and the patient makes a complete and rapid overy.

The *bronchopneumonias* conform on the whole to standard tbook descriptions.

The proportion of clinical types was:

Classical	69%	Broncho-pneumonia ..	5%
Atypical	11%	Others	5·5%
Abortive	9·5%		

The proportion regarded as atypical is small when compared with recent findings in England and America. Turner (1945) and Fleming et al. (1945) have commented on the few cases of primary atypical pneumonia encountered in the tropics, and suggest that it may be a disease of temperate climates. One case in ten was of an abortive type—a proportion higher than is usually encountered in Europeans either at home or abroad.

The period under review covered the maximum and minimum temperatures and humidities, but the incidence of pneumonia was fairly uniform. The hospital records for the preceding twelve months showed a similar distribution.

There was one death in the series, a case in which a hæmolytic anæmia, associated with well-marked sickling of the red cells, developed. Complications arose in 11 other cases: 3 had simple jaundice, 1 jaundice with a transient hemiplegia, 4 migratory pneumonia, and 1 a small sterile effusion, and the 2 others relapsed. No case of empyema occurred.

SYMPTOMS AND SIGNS

Most soldiers were recruited from the bush and could give little account of their symptoms. The West African often says simply that he is not well, or that he has "the fever," and he is apt to attribute his illness to constipation. The commonest symptoms were cough and diffuse pain in the chest: localised pain was rare and was usually associated with pleuritic rubs:

Chest pain and cough	153	Chest pain alone ..	1
Chest pain and cough and headache ..	5	Cough alone ..	6
Chest pain and headache	1	Cough and headache	2

In no case was a rigor observed. It is interesting to compare Simpson's (1944) finding that his patients rarely complained of cough.

There were signs of consolidation in the first twenty-four hours in 66 cases, and signs of late consolidation in 38; 68 did not present signs of consolidation at any time, most of these being abortive and atypical cases. In 23 cases there were signs of diffuse bronchiolitis; pleural rubs were noted in 22, and labial herpes in 12. Pleural rub and herpes were both associated mainly with a classical type of pneumonia, though 2 cases classified clinically as atypical presented both these physical signs.

BACTERIOLOGY OF SPUTUM

Pneumococci could nearly always be found among the teeming organisms of the ordinary bedside sputum pots, where bacteria flourish in a tropical climate. Patients were therefore instructed to cough and expectorate directly into a small sterilised tin, the contents of which were taken away immediately for examination and culture. By adopting this method the number recorded as having no sputum was doubtless too high; but the positive findings were more accurate, and a large proportion of pure cultures was obtained.

In 59 cases pathogenic bacteria were found in the sputum; in 47 cases there was pus only; and the remaining 66 had either no sputum (40) or saliva only (26). In 53 a pure culture of one organism was found:

Pneumococci	28	*Micrococcus catarrhalis* ..	1
Streptococcus viridans ..	20	Friedländer's bacillus ..	1
Hæmophilus influenzæ	3		

In 6 cases there were two organisms.

Pneumococci with *H. influenzæ* ..	3
Strep. viridans with *H. influenzæ* ..	2
Pneumococci with *Strep. viridans* ..	1

Of the cases in which bacteria were found 77% were of classical type. No organism was found in any case

TABLE I—WHITE-CELL COUNT AND CLINICAL TYPE

Type	White cells per c.mm.				
	Less than 5000	5000–10,000	10,000–15,000	15,000–25,000	Over 25,000
Classical	0	18	41	37	7
Atypical	3	12	2	0	0
Abortive	0	6	4	3	1
Bronchopneumonic	0	3	3	3	0
Others	0	2	5	2	0
Totals ..	3	41	55	45	8

classified clinically as atypical, although 28% had pus in the sputum. In the cases due to infection with *Strep. viridans* the clinical picture was very similar to that produced by pneumococcal infection, though rusty purulent sputum was less common.

OTHER FINDINGS

White-cell counts were carried out on 152 cases (table I).

Radiography revealed lobar involvement in 163 cases:

One lobe	89·5 %
More than one lobe	3·7 %
Negative findings	6·7 %

The types of lobar involvement are shown in table II.

The classification "segmental" was reserved for those cases, described by Graham Hodgson and others, where there is a fan-shaped opacity with its base at the periphery and its apex towards the hilum. The term "partial" was applied to cases where part only of a lobe is involved but which do not conform to any regular pattern such as central or segmental.

Of the classical cases in this table, about a third of those with involvement of a whole lobe were very mild, as were about half of those with a partial involvement, whereas 21 out of 25 of those with segmental involvement had a very benign clinical picture.

TABLE II—DISTRIBUTION OF LESIONS

Type of lobar involvement	Clinical type		
	Classical	Atypical	Abortive
Lobar	38	2	0
Partial lobar	33	7	5
Central	1	5	4
Segmental	25	5	2

Urinary Chlorides

Only about half the atypical cases had reduced urinary chlorides compared with seven-eighths of those of classical type (table III).

TABLE III—URINARY CHLORIDES

Clinical type	*Urinary chlorides*	
	Reduced	*Not reduced*
Classical	77	11
Atypical	6	5
Abortive	8	3

Blood-culture (32 cases) was undertaken before chemotherapy was begun, and blood-agar plates were used in preference to broth to enable the colonies to be counted.

Two positive results only were obtained, a pneumococcus (18 colonies per c.cm.) being isolated in one case, and a *Strep. viridans* (100 colonies per c.cm.) in the other. In the first case the moderate bacteræmia was not associated with a serious form of the disease: there was a rapid response to chemotherapy, and the patient returned to duty in 13 days.

In the second case a profuse growth of an α-hæmolytic long-chained streptococcus was associated with a classical picture, but response to chemotherapy was unsatisfactory, resolution was slow, and the patient was discharged after 38 days in hospital.

The absence of positive blood-cultures in this series is in keeping with the general mild character of the disease.

Cold agglutinins were estimated in 23 cases, but in one only—*clinically an atypical pneumonia*—was there a positive diagnostic titre.

Paul-Bunnell test (sheep's cells) was carried out in 11 cases and was negative. This test was negative in the one case where cold agglutinins were demonstrated. More recently Adams et al. (1946) have demonstrated the presence of heterophil antibodies (horse cells) in a series of cases of primary atypical pneumonia in Italy.

In all cases *blood films* were examined for malarial parasites, but they were found in only 1. During the period of investigation some hundreds of patients were admitted with malarial parasites in the blood, but only this case had any abnormal pulmonary signs. The degree of premunition in the African soldier appears to be such that a primary malarial pneumonia does not occur. Similarly, 138 patients with ascariasis were admitted, but none developed pulmonary infiltrations.

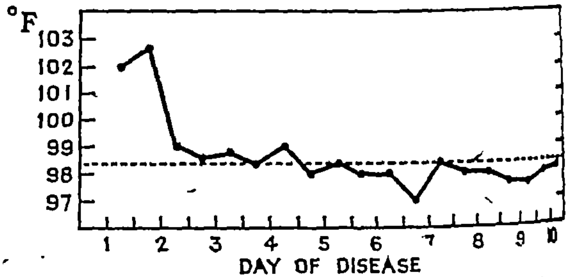

Fig. 1—Temperature chart showing early natural crisis without chemotherapy. Consolidation of whole of right upper lobe.

THERAPY AND RESPONSE

In cases receiving chemotherapy the previous routine of the hospital was followed and sulphapyridine was the standard preparation used, an initial dose of 2 g. being followed by doses of 1 g. four-hourly by day and night. The total amount given was usually 15–20 g. In English practice rather higher initial doses are often administered to produce a higher concentration of the drug in the blood, though Dick (1945) stated that in pneumococcal lobar pneumonia "there appears to be no reason for exceeding the recognised dosage of 2 g. initially, followed by 1 g. four-hourly."

Specific therapy was withheld in some cases in order to follow the natural course of the disease. As this was not considered justifiable in the more serious cases, there was inevitably some selection. The effect of this is reduced by including in table IV only cases with an initial acute chest picture and/or a temperature of over 102°F on admission:

TABLE IV—TERMINATION OF FEVER IN TREATED AND UNTREATED CASES

	Total	*Temperature fell by crisis*	*Temperature fell by lysis*
Cases receiving specific therapy ..	71	52 (74%)	19
Cases with no specific therapy ..	28	16 (57%)	12

All crises occurred within 48 hours in the treated cases, but were later in 5 of the untreated. The average duration of pyrexia in cases resolving by crisis was lower in the treated (33 hours) than in the untreated (56 hours). These figures were calculated from the time of admission es seen within a few hours of the onset of illness, re more accurate for purposes of comparison than solute records of the duration of pyrexia, which, ver, may be regarded as short by European stan-. They suggest that chemotherapy shortened the ial period in cases which resolved by crisis (see 1 and 2).

tton (1939) in Uganda and Anderson and Dowdes-1939) in Kenya found that civilian natives responded to doses of sulphapyridine similar to those used present series. Agranat (1941) concluded that in African natives response was satisfactory with r smaller doses.

LENGTH OF STAY IN HOSPITAL
